SURGICAL DEVICE HAVING MULTIPLE DRIVERS

CROSS-REFERENCE TO RELATED APPLICATIONS

The present application is a divisional of U.S. patent application Ser. No. 12/235,362, filed Sep. 22, 2008, now U.S. Pat. No. 7,963,433, which claims benefit to U.S. Provisional Patent Application No. 60/974,267, filed on Sep. 21, 2007, which is expressly incorporated herein in its entirety by reference thereto.

INCORPORATION BY REFERENCE

The present application expressly incorporates herein by reference each of the following in its entirety: U.S. patent application Ser. No. 11/191,851, filed on Jul. 27, 2005, and Issued as U.S. Pat. No. 8,241,322 on Aug. 14, 2012; U.S. patent application Ser. No. 10/460,291, filed on Jun. 11, 2003, and Issued as U.S. Pat. No. 7,743,960 on Jun. 29, 2010; U.S. patent application Ser. No. 10/099,634, filed on Mar. 15, 2002, and Issued as U.S. Pat. No. 7,951,071 on May 31, 2011; U.S. patent application Ser. No. 09/999,546, filed on Nov. 30, 2001, and Issued as U.S. Pat. No. 7,695,485 on Apr. 13, 2010; U.S. patent application Ser. No. 09/887,789, filed on Jun. 22, 2001, and Issued as U.S. Pat. No. 7,032,798 on Apr. 25, 2006; U.S. patent application Ser. No. 09/836,781, filed on Apr. 17, 2001, and Issued as U.S. Pat. No. 6,981,941 on Jan. 3, 2006; U.S. patent application Ser. No. 09/723,715, filed on Nov. 28, 2000, and Issued as U.S. Pat. No. 09/510,927, filed on Feb. 22, 2000 and Issued as U.S. Pat. No. 6,716,233 on Apr. 6, 2004.

FIELD OF THE INVENTION

The present invention relates to a surgical device. More specifically, the present invention relates to a powered, rotating and/or articulating device for clamping, cutting and stapling tissue.

BACKGROUND INFORMATION

One type of surgical device is a linear clamping, cutting and stapling device. Such a device may be employed in a surgical procedure to resect a cancerous or anomalous tissue from a gastro-intestinal tract. One conventional linear clamping, cutting and stapling instrument is shown in FIG. 1. The device includes a pistol grip-styled structure having an elongated shaft and distal portion. The distal portion includes a pair of scissors-styled gripping elements, which clamp the open ends of the colon closed. In this device, one of the two scissors-styled gripping elements, such as the anvil portion, moves or pivots relative to the overall structure, whereas the other gripping element remains fixed relative to the overall structure. The actuation of this scissoring device (the pivoting of the anvil portion) is controlled by a grip trigger maintained in the handle.

2

In addition to the scissoring device, the distal portion also includes a stapling mechanism. The fixed gripping element of the scissoring mechanism includes a staple cartridge receiving region and a mechanism for driving the staples up through the clamped end of the tissue against the anvil portion, thereby sealing the previously opened end. The scissoring elements may be integrally formed with the shaft or may be detachable such that various scissoring and stapling elements may be interchangeable.

One problem with the foregoing surgical devices, and in particular with the foregoing linear clamping, cutting and stapling devices such as that illustrated in FIG. 1, is that the opposing jaws may be difficult to maneuver within a patient. It may be necessary for a surgeon to move the opposing jaws between various angles in order to position the desired tissue between the opposing jaws. However, it is also generally desirable to make an incision in a patient that is as small as possible, and the small size of an incision limits the degree to which the opposing jaws may be maneuvered.

Another problem with the foregoing surgical devices, and in particular with the foregoing linear clamping, cutting and stapling devices such as that illustrated in FIG. 1, is that the opposing jaws may not be sufficiently hemostatic. Specifically, the opposing jaws of the foregoing surgical devices are not clamped together with sufficient force, thereby reducing the effectiveness of the surgical device. Still another problem with the foregoing surgical devices, and in particular with the foregoing linear clamping, cutting and stapling devices such as that illustrated in FIG. 1, is that the cutting and/or stapling members are not driven with sufficient torque, thereby reducing the effectiveness of the surgical device.

Thus, there is believed to be a need for an improvement in the maneuverability of clamping, cutting and stapling devices. In addition, there is believed to be a need for a clamping, cutting and stapling device that provides additional clamping, cutting and stapling forces.

SUMMARY

In accordance with an example embodiment of the present invention, a surgical device is provided, the surgical device including a first driver for performing a first movement function; a second driver for performing a second movement function; a first rotatable drive shaft configured, upon actuation, to cause selective engagement of one of the first and second drivers with a second rotatable drive shaft, wherein the second rotatable drive shaft is configured to drive the selectively engaged one of the first and second drivers.

In an embodiment, the surgical device also includes a third driver for performing a third movement function, wherein the first rotatable drive shaft is configured, upon actuation, to cause selective engagement of one of the first, second and third drivers with a second rotatable drive shaft, and wherein the second rotatable drive shaft is configured to drive the selectively engaged one of the first, second and third drivers. Also, the surgical device may include a fourth driver for performing a third movement function, wherein the first rotatable drive shaft is configured, upon actuation, to cause selective engagement of one of the first, second, third and fourth drivers with a second rotatable drive shaft, and wherein the second rotatable drive shaft is configured to drive the selectively engaged one of the first, second, third and fourth drivers.

Various movement functions may be performed by the surgical device. For example, the surgical device may include a shaft portion coupled to a handle, the handle defining a longitudinal axis. At least one of the first and second move-

3

ment functions may include rotating, upon actuation of the second rotatable drive shaft, a shaft portion of the surgical device relative to, and about a longitudinal axis of, a handle of the surgical device. Actuation of the second rotatable drive shaft in a first rotational direction may cause pivotal movement of the shaft portion in a first rotational direction relative to, and about the longitudinal axis of, the handle, and actuation of the second rotatable drive shaft in a second rotational direction may cause pivotal movement of the shaft portion in a second rotational direction that is opposite the first rotational direction relative to, and about the longitudinal axis of, the handle. The first or second driver may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In another movement function that may be performed by the surgical device, the surgical device may include a jaw portion coupled to a shaft portion, and the first or second movement function may include moving, upon actuation of the second rotatable drive shaft, a jaw portion of the surgical device relative to a shaft portion of the surgical device. Actuation of the second rotatable drive shaft in a first rotational direction may cause pivotal movement of the jaw portion in a first rotational direction relative to the shaft portion, and actuation of the second rotatable drive shaft in a second rotational direction may cause pivotal movement of the jaw portion in a second rotational direction that is opposite the first rotational direction relative to the shaft portion. The jaw portion and the shaft portion may define respective longitudinal axes, and the jaw portion may pivot relative to a shaft portion about a longitudinal axis that is perpendicular to the longitudinal axes of the jaw portion and the shaft portion. The first or second driver may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In another movement function that may be performed by the surgical device, the surgical device may include a jaw portion that includes a first jaw and a second jaw in opposed correspondence with each other, and the first or second movement function may include moving, upon actuation of the second rotatable drive shaft, the first jaw relative to the second jaw. Actuation of the second rotatable drive shaft in a first rotational direction may cause movement of the first jaw in a first rotational direction relative to the second jaw, and actuation of the second rotatable drive shaft in a second rotational direction may cause pivotal movement of the first jaw in a second rotational direction that is opposite the first rotational direction relative to the second jaw. The first or second jaws may define respective longitudinal axes, and the first jaw may pivot relative to the second jaw about a longitudinal axis that is perpendicular to the longitudinal axes of the first and second jaws. The first or second driver may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In another movement function that may be performed by the surgical device, the surgical device may include a first jaw and a second jaw in opposed correspondence with the first jaw, the second jaw including a surgical member. At least one of the first and second movement functions may include driving, upon actuation of the second rotatable drive shaft, the surgical member within the second jaw. Actuation of the second rotatable drive shaft in a first rotational direction may

4

cause movement of the surgical member in a first direction within the second jaw, and actuation of the second rotatable drive shaft in a second rotational direction may cause movement of the surgical member in a second direction that is opposite the first direction within the second jaw. The surgical member may include at least one of a cutting element and a stapling element. The first or second drivers may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In an embodiment, the first and second rotatable drive shafts are coupleable to respective drive couplings of an electro-mechanical driver. Alternatively, the surgical device may also include at least one motor, the at least one motor configured to rotate the first and second rotatable drive shafts.

In another embodiment, there is provided a surgical system that includes an electro-mechanical driver unit including at least one motor unit, and a surgical attachment that includes: a first driver for performing a first movement function; a second driver for performing a second movement function; a first rotatable drive shaft coupleable to the at least one motor unit and configured, upon actuation by the at least one motor unit, to cause selective engagement of one of the first and second drivers with a second rotatable drive shaft, wherein the second rotatable drive shaft is coupleable to the at least one motor unit and is configured to drive the selectively engaged one of the first and second drivers via the at least one motor unit.

Also, the surgical attachment of the surgical system may further include a third driver for performing a third movement function, wherein the first rotatable drive shaft is configured, upon actuation, to cause selective engagement of one of the first, second and third drivers with the second rotatable drive shaft, and wherein the second rotatable drive shaft is configured to drive the selectively engaged one of the first, second and third drivers. In addition, the surgical attachment may also include a fourth driver for performing a third movement function, wherein the first rotatable drive shaft is configured, upon actuation, to cause selective engagement of one of the first, second, third and fourth drivers with the second rotatable drive shaft, and wherein the second rotatable drive shaft is configured to drive the selectively engaged one of the first, second, third and fourth drivers.

In an embodiment, the surgical attachment of the surgical system includes a shaft portion coupled to a handle, the handle defining a longitudinal axis, wherein at least one of the first and second movement functions includes rotating, upon actuation of the second rotatable drive shaft, a shaft portion of the surgical device relative to, and about a longitudinal axis of, a handle of the surgical device. Actuation via the at least one motor unit of the second rotatable drive shaft in a first rotational direction may cause pivotal movement of the shaft portion in a first rotational direction relative to, and about the longitudinal axis of, the handle, and actuation via the at least one motor unit of the second rotatable drive shaft in a second rotational direction may cause pivotal movement of the shaft portion in a second rotational direction that is opposite the first rotational direction relative to, and about the longitudinal axis of, the handle. The first or second driver may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In an embodiment, the surgical attachment of the surgical system includes a jaw portion coupled to a shaft portion, wherein at least one of the first and second movement func-

5

tions includes moving, upon actuation via the at least one motor unit of the second rotatable drive shaft, a jaw portion of the surgical device relative to a shaft portion of the surgical device. Actuation via the at least one motor unit of the second rotatable drive shaft in a first rotational direction may cause pivotal movement of the jaw portion in a first rotational direction relative to the shaft portion, and actuation via the at least one motor unit of the second rotatable drive shaft in a second rotational direction may cause pivotal movement of the jaw portion in a second rotational direction that is opposite the first rotational direction relative to the shaft portion. The jaw portion and the shaft portion may define respective longitudinal axes, and the jaw portion may pivot relative to a shaft portion about a longitudinal axis that is perpendicular to the longitudinal axes of the jaw portion and the shaft portion. The first or second driver may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In an embodiment, the surgical attachment of the surgical system may include a jaw portion that includes a first jaw and a second jaw in opposed correspondence with each other, and the first or second movement function may include moving, upon actuation via the at least one motor unit of the second rotatable drive shaft, the first jaw relative to the second jaw. Actuation via the at least one motor unit of the second rotatable drive shaft in a first rotational direction may cause movement of the first jaw in a first rotational direction relative to the second jaw, and actuation via the at least one motor unit of the second rotatable drive shaft in a second rotational direction may cause pivotal movement of the first jaw in a second rotational direction that is opposite the first rotational direction relative to the second jaw. The first and second jaws define respective longitudinal axes, and the first jaw may pivot relative to the second jaw about a longitudinal axis that is perpendicular to the longitudinal axes of the first and second jaws. The first or second driver may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In an embodiment, the surgical attachment of the surgical system includes a first jaw and a second jaw in opposed correspondence with the first jaw, the second jaw including a surgical member, wherein at least one of the first and second movement functions includes driving, upon actuation via the at least one motor unit of the second rotatable drive shaft, the surgical member within the second jaw. Actuation via the at least one motor unit of the second rotatable drive shaft in a first rotational direction may cause movement of the surgical member in a first direction within the second jaw, and actuation via the at least one motor unit of the second rotatable drive shaft in a second rotational direction may cause movement of the surgical member in a second direction that is opposite the first direction within the second jaw. The surgical member may include at least one of a cutting element and a stapling element. The first or second driver may include at least one gear that is selectively engaged by the second rotatable drive shaft upon the first rotatable drive shaft moving a functional component into a position corresponding to the at least one of the first and second movement functions.

In an embodiment, the surgical system of the surgical system may also include a control system configured to control the motor unit. The control system may be disposed within a housing. Also, the control system may include at least one control device mounted on the surgical attachment, and the

6

control device may include a wireless remote control unit. The surgical attachment may include a position sensor corresponding to a function component that is moveable by the first rotatable drive shaft, the sensor outputting a signal corresponding to a position of the function component. The second rotatable drive shaft may be configured to be selectively engaged with the first and/or second driver based on the position of the function component.

In another embodiment, a surgical device is provided which includes a jaw portion, having a first jaw in opposed correspondence with a second jaw, the second jaw including a surgical member, a shaft portion coupled to a proximal end of the jaw portion and a handle defining a longitudinal axis. The surgical device may also include a first driver for rotating the shaft portion of the surgical device relative to, and about the longitudinal axis of, the handle; a second driver for moving the jaw portion relative to the shaft portion; a third driver for moving the first jaw relative to the second jaw; and a fourth driver for moving the surgical member within the second jaw. In addition, the surgical device may also include a first rotatable drive shaft configured, upon actuation, to cause selective engagement of at least one of the first, second, third and fourth drivers with a second rotatable drive shaft, wherein the second rotatable drive shaft is configured to drive the selectively engaged one of the first, second, third and fourth drivers.

In such an embodiment, the surgical device may be arranged such that, upon the first rotatable drive shaft causing engagement of the first driver with the second rotatable drive shaft, actuation of the second rotatable drive shaft in a first rotational direction causes pivotal movement of the shaft portion in a first rotational direction relative to, and about the longitudinal axis of, the handle, and actuation of the second rotatable drive shaft in a second rotational direction causes pivotal movement of the shaft portion in a second rotational direction that is opposite the first rotational direction relative to, and about the longitudinal axis of, the handle. Also, the surgical device may be arranged such that, upon the first rotatable drive shaft causing engagement of the second driver with the second rotatable drive shaft, actuation of the second rotatable drive shaft in a first rotational direction causes pivotal movement of the jaw portion in a first rotational direction relative to the shaft portion, and actuation of the second rotatable drive shaft in a second rotational direction causes pivotal movement of the jaw portion in a second rotational direction that is opposite the first rotational direction relative to the shaft portion. Further, the surgical device may be arranged such that the jaw portion and the shaft portion define respective longitudinal axes, and wherein the jaw portion pivots relative to a shaft portion about a longitudinal axis that is perpendicular to the longitudinal axes of the jaw portion and the shaft portion.

The surgical device may also be arranged such that, upon the first rotatable drive shaft causing engagement of the third driver with the second rotatable drive shaft, actuation of the second rotatable drive shaft in a first rotational direction causes movement of the first jaw in a first rotational direction relative to the second jaw, and actuation of the second rotatable drive shaft in a second rotational direction causes pivotal movement of the first jaw in a second rotational direction that is opposite the first rotational direction relative to the second jaw. In such an arrangement, the first and second jaws may define respective longitudinal axes, and the first jaw may pivot relative to the second jaw about a longitudinal axis that is perpendicular to the longitudinal axes of the first and second jaws.

Also, the surgical device may be arranged such that, upon the first rotatable drive shaft causing engagement of the third

driver with the second rotatable drive shaft, actuation of the second rotatable drive shaft in a first rotational direction causes movement of the surgical member in a first direction within the second jaw, and actuation of the second rotatable drive shaft in a second rotational direction causes movement of the surgical member in a second direction that is opposite the first direction within the second jaw.

In an embodiment, the first and second rotatable drive shafts may be coupleable to respective drive couplings of an electro-mechanical driver. Alternatively, the surgical device may include at least one motor, the at least one motor configured to rotate the first and second rotatable drive shafts.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a perspective view of a conventional linear clamping, cutting and stapling device;

FIG. 2(a) is a perspective view of an example embodiment of an electro-mechanical driver component, according to the present invention;

FIG. 2(b) is a schematic diagram that illustrates some of the components of a surgical device, according to an example embodiment of the present invention;

FIG. 2(c) is a schematic diagram that illustrates some of the components of a surgical device, according to another example embodiment of the present invention;

FIG. 3(a) is a perspective view of a surgical device, according to an example embodiment of the present invention;

FIG. 3(b) is a side view, partially in section, that illustrates a handle of the surgical device, according to an embodiment of the present invention;

FIG. 3(c) is a side perspective view, partially in section, that illustrates additional features of the handle of the surgical device, according to the embodiment illustrated in FIG. 3(b);

FIGS. 3(d) and 3(e) are side perspective views, partially in section, that illustrates still further features of the handle of the surgical device, according to an embodiment of the present invention;

FIG. 3(f) is a side perspective view of a distal assembly of the surgical device, according to an embodiment of the present invention;

FIG. 4(a) is an exploded perspective view that illustrates a proximal section of the distal assembly, according to the embodiment illustrated in FIG. 3(f);

FIG. 4(b) is an exploded perspective view that illustrates an intermediate section of the distal assembly, according to the embodiment illustrated in FIG. 3(f);

FIG. 4(c) is an exploded perspective view that illustrates a distal section of the distal assembly, according to the embodiment illustrated in FIG. 3(f);

FIG. 4(d) is a side perspective view, partially in section, of the intermediate section of the distal assembly, according to the embodiment illustrated in FIG. 3(f);

FIG. 4(e) is an exploded perspective view that illustrates a replaceable staple cartridge, according to an embodiment of the present invention;

FIG. 4(f) is a bottom view of the anvil of a first jaw, according to an embodiment of the present invention;

FIG. 5(a) is a side perspective view, partially in section, of the handle portion of the surgical device, and particularly the components of the handle portion that function to move, e.g., rotate, a shaft portion relative to, and about the longitudinal axis of, a handle, according to the embodiment illustrated in FIGS. 3(a) through 3(e);

FIG. 5(b) is a side perspective view, partially in section, of the handle portion of the surgical device, and particularly the components of the handle portion that function to move, e.g.,

articulate, a jaw portion relative to a shaft portion, according to the embodiment illustrated in FIGS. 3(a) through 3(e);

FIG. 5(c) is a side perspective view, partially in section, of the handle portion of the surgical device, and particularly the components of the handle portion that function to move, e.g., clamp by opening and closing, a first jaw relative to a second jaw, according to the embodiment illustrated in FIGS. 3(a) through 3(e);

FIG. 5(d) is a side perspective view, partially in section, of the handle portion of the surgical device, and particularly the components of the handle portion that function to move a cutting and/or stapling element, e.g., to drive a staple pushing element and/or cutting blade through a section of tissue, according to the embodiment illustrated in FIGS. 3(a) through 3(e);

FIG. 5(e) is a cross-sectional view of a cutting and/or stapling element of the surgical device 11, according to an embodiment of the present invention;

FIG. 6(a) is a side perspective view, partially in section, of the intermediate section of the distal portion of the surgical device, and particularly the components of the intermediate section that are moved, e.g., rotated, when a shaft portion is rotated relative to, and about a longitudinal axis of, the handle, according to the embodiment illustrated in FIGS. 3(f) and 4(d);

FIG. 6(b) is a side perspective view, partially in section, of the intermediate section of the distal portion of the surgical device, and particularly the components of the intermediate section that function to move, e.g., articulate, a jaw portion relative to a shaft portion, according to the embodiment illustrated in FIGS. 3(f) and 4(d);

FIG. 6(c) is a side perspective view, partially in section, of the intermediate section of the distal portion of the surgical device, and particularly the components of the intermediate section that function to move, e.g., clamp by opening and closing, a first jaw relative to a second jaw, according to the embodiment illustrated in FIGS. 3(f) and 4(d);

FIG. 6(d) is a side perspective view, partially in section, of the intermediate section of the distal portion of the surgical device, and particularly the components of the intermediate section that function to move a cutting and/or stapling element, e.g., to drive a staple pushing element and/or cutting blade through a section of tissue, according to the embodiment illustrated in FIGS. 3(f) and 4(d);

FIG. 7 illustrates a side view, partially in section, of the flexible shaft, according to another example embodiment of the present invention;

FIG. 8 is a cross-sectional view of the flexible shaft taken along the line 8-8 illustrated in FIG. 7;

FIG. 9 illustrates a rear end view of first coupling, according to an example embodiment of the present invention;

FIG. 10, there is seen a front end view of the second coupling of the flexible shaft, according to an example embodiment of the present invention;

FIG. 11 illustrates schematically an arrangement of motors, according to an example embodiment of the present invention;

FIG. 12 illustrates a schematic view of the electro-mechanical driver component, according to an example embodiment of the present invention;

FIG. 13 is a schematic view of an encoder, according to an example embodiment of the present invention;

FIG. 14 schematically illustrates the memory module, according to an example embodiment of the present invention;

FIG. 15, there is seen a schematic view of a wireless RCU, according to an example embodiment of the present invention;

FIG. 16, there is seen a schematic view of a wired RCU, according to an example embodiment of the present invention;

FIG. 17(a) is a side perspective view of such a surgical device, according to an example embodiment of the present invention;

FIG. 17(b) is a partial cutaway view of the surgical device of FIG. 17(a), showing additional details of the components internal to the handle;

FIG. 17(c) is a partially cutaway, top perspective view of the surgical device of FIG. 17(a), which illustrates additional details of the drive mechanism;

FIG. 18(a) is an exploded perspective view of a selector gearbox assembly;

FIG. 18(b) is a cross-sectional view of the selector gearbox assembly of FIG. 18(a);

FIG. 18(c) is a perspective view of the selector gearbox assembly of FIG. 18(a); and

FIG. 18(d) is a front view of the selector gearbox assembly of FIG. 18(a).

DETAILED DESCRIPTION

FIG. 2(b) is a schematic diagram that illustrates some of the components of a surgical device 11, according to an example embodiment of the present invention. The surgical device 11 is configured so as to be particularly well-suited for insertion into the body of a patient, e.g., via a cannula (not shown). In the embodiment shown, the surgical device 11 is a clamping, cutting and stapling device. The surgical device 11 includes a jaw portion 11a that is pivotably coupled to a shaft portion 11b by a hinge portion 11c. The jaw portion 11a includes a first jaw 50 having a distal end 50a and a proximal end 50b, and a second jaw 80 having a distal end 80a and a proximal end 80b. The first jaw 50 and the second jaw 80 are pivotably coupled relative to each other at or near their respective proximal ends 50b, 80b. As shown, the first jaw 50 and the second jaw 80 are pivotable relative to each other about pivot axis A. In the example embodiment shown, pivot axis A is oriented perpendicular to the page. In this arrangement, the jaws are configured such that, upon opening and closing of the first jaw 50 relative to the second jaw 80 and at point in the movement of the first jaw 50 relative to the second jaw 80, both the first jaw 50 and the second jaw 80, e.g., their longitudinal axes, remain within a plane defined by the page. It should be understood, however, that the surgical device 11 may instead be configured such that the first jaw 50 and the second jaw 80 are pivotable relative to each other about a pivot axis that is not oriented perpendicular to the page, in which case the first jaw 50 and the second jaw 80 may move within a plane or planes defined by other than the page.

As mentioned above, the jaw portion 11a is pivotably coupled to the shaft portion 11b by the hinge portion 11c. Specifically, the jaw portion 11a is pivotable relative to the shaft portion 11b about a pivot axis B, which may be positioned at any location on or between the jaw portion 11a and the shaft portion 11b, and at any circumferential location relative to the jaw portion 11a and the shaft portion 11b. In the example embodiment shown, the pivot axis B is oriented vertically, and within the page, in the view shown. In this arrangement, the jaw portion 11a and the shaft portion 11b are configured such that, upon articulation of the jaw portion 11a relative to the shaft portion 11b and at any point in the movement of the jaw portion 11a relative to the shaft portion

11b, the jaw portion 11a and the shaft portion 11b remain within a plane that is perpendicular to the pivot axis B. It should be recognized that, in other example embodiments, the pivot axis B may have a different orientation, so as to enable the jaw portion 11a to pivot within a different plane. The jaw portion 11a may be pivotable to and between any angles relative to the shaft portion 11b, such that the jaw portion 11a can be selectively positioned as desired during use.

Furthermore, the surgical device 11 may provide rotation of various components about a longitudinal axis of the surgical device 11. For example, in various embodiments, the jaw and/or shaft portions 11a, 11b may be rotatable relative to a handle 1103 (described in additional detail below), that is attached to a proximal end of the shaft portion 11b, about a longitudinal axis D of the handle 1103, e.g., the longitudinal axis D of the handle 1103 at the point where the handle 1103 meets the shaft portion 11b.

The shaft portion 11b may include a distal portion 1101a, to which the jaw portion 11a is connected, and a proximal portion 1101b, which may be connected to the handle 1103. For the purposes of clarity, the handle 1103 is shown in FIG. 2(b) schematically; further details of the handle 1103, according to various embodiments of the present invention, are set forth in connection with, e.g., FIGS. 5(a) through 5(d). Generally, the handle 1103 provides a device with which a user may grasp and operate the surgical device 11. The handle 1103 has a proximal portion 1102. At the proximal portion 1102, the handle 1103 may include a connection element 1104, e.g., a quick-connect coupling, for connecting to a flexible shaft (described in further detail below).

The second jaw 80 includes a clamping surface 106. The second jaw 80 also includes a cutting and stapling element 104, which may form at least part of the clamping surface 106 of the second jaw 80. The first jaw 50 includes an anvil member 700 in opposed correspondence with the second jaw 80. The anvil member 700 includes the clamping surface 108, which, along with the clamping surface 106 of the second jaw 80, clamps a section of tissue to be cut and stapled. As explained in greater detail below, the cutting and stapling element 104 is configured to cut and staple a section of tissue when the first jaw 50 and the second jaw 80 are in a closed, e.g., fully closed, position. Additional features of the cutting and stapling element 104, according to an embodiment, are illustrated and described, for instance, in connection with FIGS. 3(f) and 3(g) below, and further in U.S. patent application Ser. No. 09/999,546, filed Nov. 30, 2001 (now U.S. Pat. No. 7,695,485), and U.S. patent application Ser. No. 10/460,291, filed Jun. 11, 2003 (now U.S. Pat. No. 7,743,960), each of which, as set forth above, are hereby expressly incorporated herein by reference in their entirety.

Various drivers may be employed to drive the movements of the surgical device 11, e.g., pivoting the first jaw 50 relative to the second jaw 80, firing of a staple cartridge, pivoting the jaw portion 11a relative to the shaft portion 11b, rotating the jaw and shaft portions 11a, 11b or some part thereof around the longitudinal axis of the shaft portion 11b, etc. According to an embodiment of the present invention, these functions are performed by connection of the surgical device 11 to a flexible shaft having two rotatable drive shafts, although it should be recognized that in other embodiments, different types and/or a different number of drive components may be employed.

FIG. 2(b) illustrates schematically that the handle 1103 includes a function selector module 1110. Additional details of the function selector module 1110 are set forth below. Generally, the function selector module 1110 is actuatable by a first rotatable drive shaft 1110a so as to move between a

11

plurality of different functional positions. In the embodiment shown, the function selector module **1110** is actuatable by the first rotatable drive shaft **1110a** between four different functional positions, each of which is set forth more fully below. The function selector module **1110** is configured such that, in each one of the different functional positions, the function selector module **1110** causes engagement of a second rotatable drive shaft **1110b** with a selected one of various drivers **88, 98, 201, 202** of the surgical device **11**. Each one of the drivers **88, 98, 201, 202** is configured to perform, upon engagement with and operation of the second rotatable drive shaft **1110b**, a particular function of the surgical device **11**, as set forth below.

As set forth above, in the embodiment shown in FIG. 2(b), the handle **1103** includes a connection element **1104**, which enables the first rotatable drive shaft **1110a** to be coupled to the third rotatable drive shaft **94** via the first drive socket **654**. The third rotatable drive shaft **94** is in turn coupled to, or coupleable to, a first motor **96**. In this manner, operation of the first motor **96** to rotate the third rotatable drive shaft **94**, the first drive socket **654** and first rotatable drive shaft **1110a** may actuate the function selection module **1110**.

Also, in the embodiment shown in FIG. 2(b), the connection element **1104** of the handle **1103** may enable the second rotatable drive shaft **1110b** to be coupled to a fourth rotatable drive shaft **102** via a second drive socket **694**. The fourth rotatable drive shaft **102** is in turn coupled to, or coupleable to, a second motor **100**. In this manner, operation of the second motor **100** to rotate the fourth rotatable drive shaft **102**, the second drive socket **694** and second rotatable drive shaft **1110b** may drive the particular driver mechanism that has previously been selected by the operation of the function selection module **1110**.

In an embodiment, a first function that may be performed by the surgical device **11** is to rotate the shaft portion **11b** about longitudinal axis D relative to the handle **1103**, e.g., to operate a rotation gear within the handle **1103** so as to rotate the shaft portion **11b** about longitudinal axis D relative to the handle **1103**. To perform this function, the function selection module **1110** may initially be positioned in a first selection position by the actuation of the first rotatable drive shaft **1110a** by the first motor **96** (and by the rotation of third rotatable drive shaft **94** and the first drive socket **654** engaged therebetween). Once the function selection module **1110** is positioned in the first selection position, the function selection module **1110** causes the rotation driver **202** to be engaged with the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), such that operation of the second motor **100** actuates the rotation driver **202**. In the embodiment described herein, the rotation driver **202**, when actuated by the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), may operate to rotate the shaft portion **11b** about longitudinal axis D relative to the handle **1103**, e.g., to operate a rotation gear within the handle **1103** so as to rotate the shaft portion **11b** about longitudinal axis D relative to the handle **1103**, in addition to performing other operations of the surgical device **11**. The rotation driver **202** may include any type of drive mechanism capable of rotating the shaft portion **11b** about longitudinal axis D relative to the handle **1103**, e.g., of operating a rotation gear within the handle **1103** so as to rotate the shaft portion **11b** about longitudinal axis D relative to the handle **1103**. The rotation driver **202** may be situated in the distal portion of the handle **1103** and may engage the shaft portion **11b** for the purposes of moving the shaft portion **11b** relative to the handle **1103**. Additional details of the rotation driver **202**, in

12

accordance with an example embodiment of the present invention, are set forth in greater detail below.

In an embodiment, a second function that may be performed by the surgical device **11** is to move the jaw portion **11a** relative to the shaft portion **11b**, e.g., to pivot the jaw portion **11a** about axis B relative to the shaft portion **11b**. To perform this function, the function selection module **1110** may initially be positioned in a second selection position by the actuation of the first rotatable drive shaft **1110a** by the first motor **96** (and by the rotation of third rotatable drive shaft **94** and the first drive socket **654** engaged therebetween). Once the function selection module **1110** is positioned in the second selection position, the function selection module **1110** causes the articulation driver **201** to be engaged with the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), such that operation of the second motor **100** actuates the articulation driver **201**. In the embodiment described herein, the articulation driver **201**, when actuated by the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), may operate to move the jaw portion **11a** relative to the shaft portion **11b**, e.g., to pivot the jaw portion **11a** about axis B relative to the shaft portion **11b**, in addition to performing other operations of the surgical device **11**. The articulation driver **201** may include any type of drive mechanism capable of the jaw portion **11a** relative to the shaft portion **11b**, e.g., to pivot the jaw portion **11a** about axis B relative to the shaft portion **11b**. The articulation driver **201** may be situated in the distal portion **1101a** of the shaft portion **11b** and may engage the jaw portion **11a** for the purposes of moving the jaw portion **11a** relative to the shaft portion **11b**. Additional details of the articulation driver **201**, in accordance with an example embodiment of the present invention, are set forth in greater detail below.

In an embodiment, a third function that may be performed by the surgical device **11** is to move, e.g., open and close by pivoting or any other conceivable relative movement, the first jaw **50** relative to the second jaw **80**. To perform this function, the function selection module **1110** may initially be positioned in a third selection position by the actuation of the first rotatable drive shaft **1110a** by the first motor **96** (and by the rotation of third rotatable drive shaft **94** and the first drive socket **654** engaged therebetween). Once the function selection module **1110** is positioned in the third selection position, the function selection module **1110** causes the clamping driver **88** to be engaged with the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), such that operation of the second motor **100** actuates the clamping driver **88**. In the embodiment described herein, the clamping driver **88**, when actuated by the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), may operate to move, e.g., open and close, the first jaw **50** relative to the second jaw **80**, in addition to performing other operations of the surgical device **11**. The clamping driver **88** may include any type of drive mechanism capable of moving the first jaw **50** and the second jaw **80** relative to each other. The clamping driver **88** may be situated at least partially in the proximal end **80b** of the second jaw **80** and may be connected to the proximal end **50b** of the first jaw **50** so as to engage the proximal end **50b** of the first jaw **50** for opening and closing the first jaw **50** relative to the second jaw **80**. Additional details of the clamping driver **88**, in accordance with an example embodiment of the present invention, are set forth in greater detail below.

In an embodiment, a fourth function that may be performed by the surgical device **11** is to move a cutting and/or stapling

13

element, e.g., to drive a staple pushing element and/or cutting blade through a section of tissue such as by turning a threaded drive shaft of the cutting and stapling element **104**. To perform this function, the function selection module **1110** may initially be positioned in a fourth selection position by the actuation of the first rotatable drive shaft **1110a** by the first motor **96** (and by the rotation of third rotatable drive shaft **94** and the first drive socket **654** engaged therebetween). Once the function selection module **1110** is positioned in the fourth selection position, the function selection module **1110** causes the firing driver **98** to be engaged with the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), such that operation of the second motor **100** actuates the second driver **88**. In the embodiment described herein, the second driver **88**, when actuated by the second motor **100** (via the fourth rotatable drive shaft **102** and the second drive socket **694** engaged therebetween), may operate to move a cutting and/or stapling element, e.g., to drive a staple pushing element and/or cutting blade through a section of tissue, in addition to performing other operations of the surgical device **11**. The firing driver **98** may include any type of drive mechanism capable of moving a cutting and/or stapling element, e.g., driving a staple pushing element and/or cutting blade through a section of tissue. The firing driver **88** may be situated between the proximal end **80b** and the distal end **80a** of the second jaw **80** so as to cut and/or staple a section of tissue disposed between the first jaw **50** and the second jaw **80**. Additional details of the firing driver **98**, in accordance with an example embodiment of the present invention, are set forth in greater detail below.

It should be recognized that, while two drive sockets, e.g., the first drive socket **654** and the second drive socket **694**, and two corresponding drive shafts, e.g., the first drive shaft **94** and the second drive shaft **102**, are illustrated as being part of the surgical device **11** and as being for the purposes of, e.g., moving and positioning certain components of the surgical device **11** relative to other components and/or clamping, cutting and stapling a section of tissue, it is possible to provide any suitable number of drive sockets and drive shafts. For example, a single drive shaft, or more than two drive shafts, may be provided to perform the above-described functions of the surgical device **11**.

The drive shafts, e.g., the first and second rotatable drive shafts **94** and **102** and any other drive shafts, may be housed within a flexible drive shaft, such as the flexible drive shaft **1620** illustrated in FIG. **2(a)**. Other types of flexible drive shafts may also be employed. For instance, the drive shafts may be housed within a flexible drive shaft of the type described and illustrated in U.S. Provisional Patent Application No. 60/703,227, filed Jul. 27, 2006 and entitled "Flexible Shaft for an Electro-Mechanical Surgical Device," which is expressly incorporated by reference herein in its entirety.

Referring to FIG. **2(b)**, the surgical device **11** may also include a memory module **6041**. In an embodiment, the memory module **6041** is connected to or integral with the cutting and stapling element **104**. The memory module **6041** is connected to a data connector **1272** by a data transfer cable **1278**. Additional features of these components are set forth in connection with, e.g., FIGS. **3(f)** and **7**.

Furthermore, FIG. **2(b)** also illustrates a connection element **1104**. The connection element **1104** may include a quick connect sleeve **713** that has quick connect slots **713a** that engage complementary quick connect elements **1664** of a flexible drive shaft **1620**, which is described in further detail below. In order to retain the quick connect elements **1664** of

14

the flexible drive shaft **1620** in the quick connect slots **713a** of the quick connect sleeve **713**, the connection element **1104** may also include a spring.

Also, it should be recognized that the motors employed to drive the first and second rotatable drive shafts **1110a** and **1110b** may be integral with the surgical device **11**. For example, FIG. **2(c)** is a schematic diagram that illustrates an alternative arrangement of the surgical device **11**, according to another example embodiment of the present invention. In this embodiment, first motor **961** and second motor **1001** are arranged within the handle **1103**, such that the first and second rotatable drive shafts **1110a** and **1110b** are connected to the first and second motors **961**, **1001**, respectively.

According to an example embodiment of the present invention, the surgical device **11** may be configured as an attachment to, or may be integral with, an electro-mechanical surgical system, such as the electro-mechanical driver component **1610** having a motor system illustrated in FIG. **2(a)**. It should be appreciated that, in this example embodiment, any appropriate number of motors may be provided, and the motors may operate via battery power, line current, a DC power supply, an electronically controlled DC power supply, etc. It should also be appreciated that the motors may be connected to a DC power supply, which is in turn connected to line current and which supplies the operating current to the motors. In another example embodiment, the surgical device may be an attachment to, or may be integral with, a mechanical driver system.

FIG. **3(a)** is a perspective view of a surgical device **11**, according to an embodiment of the present invention. As set forth above, FIGS. **3(a)** to **3(e)** illustrate an embodiment of the present invention in which two drive shafts are configured to be employed to rotate the shaft portion **11b** relative to, and about the longitudinal axis of, the handle **1103**; to move, e.g., articulate, the jaw portion **11a** relative to the shaft portion **11b**; to move, e.g., open or close, the first jaw **50** relative to the second jaw **80**; and to fire a stapling and cutting cartridge. In the position shown in FIG. **3(a)**, the jaw portion **11a** is positioned at an angle of approximately 60 degrees relative to the shaft portion **11b**. The jaw portion **11a** may be appropriately positioned according to the incision made in the patient and to the position of the tissue desired to be clamped, cut and/or stapled.

As set forth above, FIG. **3(b)** is a side view, partially in section, that illustrates the handle **1103** of the surgical device, according to an embodiment of the present invention. FIG. **3(c)** is a side perspective view, partially in section, that illustrates additional features of the handle of the surgical device, according to the embodiment illustrated in FIG. **3(b)**. FIGS. **3(d)** and **3(e)** are side perspective views, partially in section, that illustrates still further features of the handle of the surgical device, according to an embodiment of the present invention.

Referring now to FIG. **3(b)**, it is illustrated that the handle **1103** includes the first rotatable drive shaft **1110a** which extends from a proximal end of the handle **1103** inwardly. The first rotatable drive shaft **1110a** has a longitudinally-arranged bore in which a proximal end of a selector shaft **601** is arranged. Advantageously, the longitudinally-arranged bore of the first rotatable drive shaft **1110a** and the proximal end of a selector shaft **601** are correspondingly sized and shaped such that, when engaged, rotation of the first rotatable drive shaft **1110a** causes rotation of the selector shaft **601**. In addition, the proximal end of the selector shaft **601** is inserted through a spring **603**, and is maintained in position between a longitudinal stop of the selector shaft **601** and the first rotat-

15

able drive shaft 1110a. The spring 603 functions to bias the first rotatable drive shaft 1110a in a proximal direction.

A distal-most end of the selector shaft 601 is rotatably mounted within an orifice of a fixed interior wall 605 of the handle, the fixed interior wall 605 of the handle 1103 being perpendicular to the longitudinal axis of the selector shaft 601. The selector shaft 601 also includes, along a length that is adjacent to the distal-most end thereof, a threaded portion 607. A function selector block 609 has a threaded bore that extends longitudinally therethrough. The threaded portion 607 of the selector shaft 601 extends through the threaded bore of the function selector block 609 such that the function selector block 609 is mounted thereon. The function selector block 609 is keyed to an interior surface of the handle such that, upon rotation of the selector shaft 601, the threaded engagement of the threaded portion 607 of the selector shaft 601 within the threaded bore of the function selector block 609 causes the function selector block 609 to move distally and proximally along the selector shaft 601.

FIG. 3(b) also illustrates that the handle 1103 includes the second rotatable drive shaft 1110b which extends from a proximal end of the handle 1103 inwardly. The second rotatable drive shaft 1110b has a longitudinally-arranged bore into which a proximal end of a function shaft 611 is arranged. Advantageously, the longitudinally-arranged bore of the second rotatable drive shaft 1110b and the proximal end of the function shaft 611 are correspondingly sized and shaped such that, when engaged, rotation of the second rotatable drive shaft 1110b causes rotation of the function shaft 611. In addition, the proximal end of the function shaft 611 is inserted through a spring 613, and is maintained in position between a longitudinal stop of the function shaft 611 and the second rotatable drive shaft 1110b. The spring 613 functions to bias the second rotatable drive shaft 1110b in a proximal direction.

A distal-most end of the function shaft 611 is rotatably mounted within an orifice of a fixed interior wall 615 of the handle, the fixed interior wall 615 of the handle 1103 being perpendicular to the longitudinal axis of the function shaft 611. The function shaft 611 also includes, along a length that is adjacent to the distal-most end thereof, a fire spur gear 617. Located along the function shaft 611 in a position that is proximal relative to the fire spur gear 617 is an input spur gear 619. The fire spur gear 617 and the input spur gear 619 each have respective outer circumferential gear teeth 6171, 6191. Also rotatably mounted within an orifice of a fixed interior wall 615 of the handle is a secondary fire spur gear 618. The secondary fire spur gear 618 has outer circumferential gear teeth 6181 that are meshingly engaged with the outer circumferential gear teeth 6191 of the fire spur gear 619.

Extending distally from the function selector block 609 is a gear shaft 621. Arranged at varying longitudinal positions along the gear shaft 621 are various gears. For example, at a longitudinal position along the gear shaft 621 that is most nearly adjacent to the function selector block 609 is a rotation spur gear 623. The rotation spur gear 623 includes outer circumferential gear teeth 6231. The outer circumferential gear teeth 6231 engage the outer circumferential gear teeth 6191 of the input spur gear 619. In an embodiment, the rotation spur gear 623 and the input spur gear 619 provides a 4:1 gear ratio relative to each other. Of course, it should be recognized that any suitable gear ratio may be employed. Also, at a longitudinal position along the gear shaft 621 that is distal relative to the rotation spur gear 623 is a fire spur gear 625. The fire spur gear 625 includes outer circumferential gear teeth 6251. The outer circumferential gear teeth 6251 of the fire spur gear 625 engage the outer circumferential gear teeth 6171 of the fire spur gear 617. In addition, at a longitudi-

16

dinal position along the gear shaft 621 that is distal relative to the fire spur gear 625 is a clamping spur gear 627. The clamping spur gear 627 includes outer circumferential gear teeth 6271. At a longitudinal position along the gear shaft 621 that is distal relative to the clamping spur gear 627 is an articulation spur gear 629. The articulation spur gear 629 includes outer circumferential gear teeth 6291. Still further, at a longitudinal position along the gear shaft 621 that is distal relative to the articulation spur gear 629 is a rotation spur gear 631. The rotation spur gear 631 includes outer circumferential gear teeth 6311.

The handle 1103 also includes a rotation gear shaft 633. A proximal end of the rotation gear shaft 633 is rotatably mounted within an orifice of a fixed interior wall 635 of the handle 1103, the fixed interior wall 635 of the handle 1103 being generally perpendicular to the longitudinal axis of the rotation gear shaft 633. A distal end of the rotation gear shaft 633 is rotatably mounted within an orifice of a fixed interior wall 637 of the handle 1103, the fixed interior wall 637 of the handle 1103 also being generally perpendicular to the longitudinal axis of the rotation gear shaft 633. The rotation gear shaft 633 includes, along a length that is adjacent to its proximal end, a rotation spur gear 639. The rotation spur gear 639 has outer circumferential gear teeth 6391. The rotation gear shaft 633 also includes, along a length that is adjacent to its distal end, a rotation worm gear 641. The rotation worm gear 641 has outer circumferential worm gear teeth 6411.

A rotation gear 643 is rotatably mounted to a fixed interior wall 645 of the handle 1103. Advantageously, the rotation gear 643 is rotatably mounted about a pivot axis that is perpendicular to a longitudinal axis of the rotation gear shaft 633. The rotation gear 643 has outer circumferential gear teeth 6431 that are meshingly engaged with the outer circumferential worm gear teeth 6411 of the rotation worm gear 641. In an embodiment, the rotation gear 643 and the rotation worm gear 641 provide a 45:1 gear ratio relative to each other. Of course, it should be recognized that any suitable gear ratio may be employed. Mounted to a surface of the rotation gear 643, and configured to rotate therewith, is a rotation miter gear 644. The rotation miter gear 644 has miter gear teeth 6441.

The handle 1103 also includes a second rotation gear shaft 665. The second rotation gear shaft 665 is maintained within the handle 1103 by a channel 667 in which the second rotation gear shaft 665 is longitudinally and rotatably maintained. A proximal end of the second rotation gear shaft 665 includes a rotation miter gear 669. The rotation miter gear 669 has miter gear teeth 6691. The miter gear teeth 6691 of the rotation miter gear 669 are meshingly engaged with the miter gear teeth 6441 of the miter gear 644.

A distal end of the second rotation gear shaft 665 is rotatably mounted within an orifice of a fixed interior wall 671 of the handle 1103, the fixed interior wall 671 of the handle 1103 being generally perpendicular to the longitudinal axis of the second clamping gear shaft 665. The second rotation gear shaft 665 also includes, along a length that is adjacent to its distal end, a rotation spur gear 673. The rotation spur gear 673 has outer circumferential gear teeth 6731.

Mounted within a mouth 675 at the distal-most end of the handle 1103 is a rotating tube 677. Longitudinal stops maintain the rotating tube 677 longitudinally within the mouth 675. The distal end of the rotating tube 677 extends to the tube housing 523. The proximal end of the rotating tube 677 includes a rotating tube spur gear 679. The rotating tube spur gear 679 has outer circumferential gear teeth 6791. The outer circumferential gear teeth 6791 of the rotating tube spur gear 679 are meshingly engaged with the outer circumferential gear teeth 6731 of the rotation spur gear 673. In an embodi-

17

ment, the rotation spur gear **673** and the rotating tube spur gear **679** provides a 1.4:1 gear ratio relative to each other. Of course, it should be recognized that any suitable gear ratio may be employed.

FIG. **5(b)** illustrates, partially in section, a side perspective view that is opposite from the side view provided in FIG. **3(b)**. FIG. **5(b)** illustrates additional components of the handle **1103** that are hidden from view in FIG. **3(b)**. Referring now to FIG. **5(b)**, there is shown an articulation gear shaft **685**. A proximal end of the articulation gear shaft **685** is rotatably mounted within an orifice of a fixed interior wall (shown in phantom) of the handle **1103**, the fixed interior wall of the handle **1103** being generally perpendicular to the longitudinal axis of the articulation gear shaft **685**. A distal end of the articulation gear shaft **685** is rotatably mounted within an orifice of another fixed interior wall (also shown in phantom) of the handle **1103**, this fixed interior wall of the handle **1103** also being generally perpendicular to the longitudinal axis of the articulation gear shaft **685**. The articulation gear shaft **685** includes, along a length that is adjacent to its proximal end, an articulation spur gear **687**. The articulation spur gear **687** has outer circumferential gear teeth **6871**. The outer circumferential gear teeth **6871** of the articulation spur gear **687** are meshingly engaged with the outer circumferential gear teeth **6291** of the articulation spur gear **629**. The articulation gear shaft **685** also includes, along a length that is adjacent to its distal end, articulation worm gear **689**. The articulation worm gear **689** has outer circumferential worm gear teeth **6891**.

An articulation gear **691** is rotatably mounted to a fixed interior wall **693** of the handle **1103**. Advantageously, the articulation gear **691** is rotatably mounted about a pivot axis that is perpendicular to a longitudinal axis of the articulation gear shaft **685**. The articulation gear **691** has outer circumferential gear teeth **6911** that are meshingly engaged with the outer circumferential worm gear teeth **6891** of the articulation worm gear **689**. In an embodiment, the articulation gear **691** and the articulation worm gear **689** provide a 11.25:1 gear ratio relative to each other. Of course, it should be recognized that any suitable gear ratio may be employed.

Referring back again to FIG. **3(b)**, there are shown additional features of the handle **1103** that contribute to the articulation function. For example, mounted to a surface of the articulation gear **691**, and configured to rotate therewith, is a first articulation miter gear **692**. The first articulation miter gear **692** has miter gear teeth **6921**.

The handle **1103** also includes a second articulation gear shaft **693**. The second articulation gear shaft **693** is rotatably maintained within the handle **1103** by a channel **694**. A proximal end of the second articulation gear shaft **693** forms a threaded rod **695**. Mounted on the threaded rod **695** is a second articulation miter gear **696**, which is mounted within the handle **696** by an articulation miter gear support **697**. The second articulation miter gear **696** has miter gear teeth **6961**. The miter gear teeth **6961** of the second articulation miter gear **696** are meshingly engaged with the miter gear teeth **6921** of the first articulation miter gear **692**. The articulation gear support **697** maintains the longitudinal and radial positions of the second articulation miter gear **696** within the handle **1103**, while allowing the second articulation miter gear **696** to rotate about its longitudinal axis. The second articulation miter gear **696** defines a longitudinally-arranged threaded bore, the threaded rod **695** of the second articulation gear shaft **693** engaging the longitudinally-arranged threaded bore of the second articulation miter gear **696**.

The distal end of the second articulation gear shaft **693** extends through a longitudinally-defined opening through the center region of the rotating tube spur gear **679** and passes

18

through the rotating tube **677** at the mouth **675** of the handle **1103** so as to eventually form the articulation shaft **525** (as shown in FIG. **4(a)**). By virtue of the threaded engagement between the threaded rod **695** of the second articulation gear shaft **693** and the longitudinally-arranged threaded bore of the second articulation miter gear **696**, rotation of the second articulation miter gear **696** causes selective movement in either a distal or proximal direction of the second articulation gear shaft **693** relative to the handle **1103**.

Referring to FIG. **3(b)**, the handle **1103** also includes a clamping gear shaft **651**. A proximal end of the clamping gear shaft **651** is rotatably mounted within an orifice of a fixed interior wall **653** of the handle **1103**, the fixed interior wall **653** of the handle **1103** being generally perpendicular to the longitudinal axis of the clamping gear shaft **651**. The clamping gear shaft **651** includes, along a length that is adjacent to its distal end, a clamping spur gear **655**. The clamping spur gear **655** has outer circumferential gear teeth **6551**. The clamping gear shaft **651** also includes at its distal end a first clamping miter gear **657**. The first clamping miter gear **657** has miter gear teeth **6571**.

A second clamping miter gear **659** is rotatably mounted to a fixed interior wall **663** of the handle **1103**. Advantageously, the second clamping miter gear **659** is rotatably mounted about a pivot axis that is perpendicular to a longitudinal axis of the clamping gear shaft **651**. The second clamping miter gear **659** has miter gear teeth **6591** that are meshingly engaged with the miter gear teeth **6571** of the first clamping miter gear **657**.

Also, the handle **1103** includes a second clamping gear shaft **681**. A proximal end of the second clamping gear shaft **681** includes a third clamping miter gear **661**. The third clamping miter gear **661** has miter gear teeth **6611** that are meshingly engaged with the miter gear teeth **6591** of the second clamping miter gear **659**. The distal end of the second clamping gear shaft **681** extends through a longitudinally-defined opening through the center region of the rotating tube spur gear **679** and passes through the rotating tube **677** at the mouth **675** of the handle **1103** so as to eventually form the clamping shaft **527** (as shown in FIG. **4(a)**).

Referring to FIG. **3(b)**, the handle **1103** also includes a firing gear shaft **604**. Adjacent to its proximal end, the firing gear shaft **604** is rotatably mounted within an orifice of a fixed interior support **606** of the handle **1103**, the fixed interior support **604** of the handle **1103** including as its distal surface the fixed interior wall **606** into which the distal end of function shaft **611** is rotatably mounted. The firing gear shaft **604** includes, at its proximal end, a firing spur gear **608**. The firing spur gear **608** has outer circumferential gear teeth **6081**. The outer circumferential gear teeth **6081** of the firing spur gear **608** are meshingly engaged with the outer circumferential gear teeth **6171** of the firing spur gear **617**.

FIG. **5(d)** illustrates, partially in section, a side perspective view that is opposite from the side view provided in FIG. **3(b)**. FIG. **5(d)** illustrates additional components of the handle **1103** that are hidden from view in FIG. **3(b)**. Referring now to FIG. **5(d)**, the firing gear shaft **604** includes, at its distal end, a first firing miter gear **610**. The first firing miter gear **610** has miter gear teeth **6101**.

A second firing miter gear **612** is rotatably mounted to a fixed interior wall **616** of the handle **1103**. Advantageously, the second firing miter gear **612** is rotatably mounted about a pivot axis that is perpendicular to a longitudinal axis of the firing gear shaft **604**. The second firing miter gear **612** has miter gear teeth **6121** that are meshingly engaged with the miter gear teeth **6101** of the first firing miter gear **610**.

19

Also, the handle **1103** includes a second firing gear shaft **618**. A proximal end of the second firing gear shaft **618** includes a third firing miter gear **614**. The third firing miter gear **614** has miter gear teeth **6141** that are meshingly engaged with the miter gear teeth **6121** of the second firing miter gear **612**. The distal end of the second firing gear shaft **618** extends through a longitudinally-defined opening through the center region of the rotating tube spur gear **679** and passes through the rotating tube **677** at the mouth **675** of the handle **1103** so as to eventually form the firing shaft **529** (as shown in FIG. 4(a)).

FIG. 3(b) also illustrates that, in accordance with an embodiment of the present invention, the surgical device **11** may include optical function sensors **3001**, **3002**, **3003** and **3004**. These optical sensors **3001**, **3002**, **3003** and **3004** may each include a diode, e.g., LEDs, that provides light out of a respective hole of wall **3005**. Movement of the function selector block **609** via the threaded portion **607** of the selector shaft **601**, selectively blocks the transmission of light from one of the diodes of the sensors **3001**, **3002**, **3003** and **3004**. This blocking of the transmission of light enables the surgical device **11** to determine which one of the four above-described functional positions the function selector block **609** is in, and therefore to control the operation of the surgical device **11** accordingly. In other words, depending on the position of the function selector block **609**, corresponding signals to and from various ones of the optical sensors **3001**, **3002**, **3003** and **3004** are blocked, thereby providing a suitable controller with an indication when the surgical device **11** is satisfactorily positioned in one of the four above-described functional positions, e.g., rotation, articulation, opening/closing of the jaws relative to each other, and firing the cutting and/or stapling mechanism.

FIG. 3(b) also illustrates that, in accordance with an embodiment of the present invention, the surgical device **11** may include a rotation/articulation control device **3006**. In an embodiment, the rotation/articulation control device **3006** may be a joystick-type device that is suitably positioned, e.g., on a top surface of the handle **1103**, and sized so as to be actuable by an operator's thumb when the operator is holding the handle **1103**. Also, FIG. 3(b) illustrates that, in accordance with an embodiment of the present invention, the surgical device **11** may include an open/close/fire control device **3007**. In an embodiment, the open/close/fire control device **3007** may be a trigger-type device that is suitably positioned, e.g., on a bottom surface of the handle **1103**, and sized so as to be actuable by an operator's forefinger when the operator is holding the handle **1103**. The operation of the rotation/articulation control device **3006** and the open/close/fire control device **3007** are described in addition detail below.

FIGS. 3(f), 4(a) through 4(c) and 4(d) collectively illustrate the components of the surgical device that are distal relative to the handle **1103**. For example, FIG. 3(f) is a side perspective view of a distal assembly of the surgical device **11**, as assembled, according to an embodiment of the present invention. FIG. 4(a) is an exploded perspective view that illustrates a proximal section of this distal assembly, according to the embodiment illustrated in FIG. 3(f).

For example, FIG. 4(a) illustrates a proximal pivot housing **503** having a pair of longitudinally arranged orifices, each one of which is configured to receive a respective one of a pair of threaded screws **501a**, **501b**. The proximal pivot housing **503** also houses a pair of input bevel gears **505a**, **505b**, each one of which is configured to be inserted into a respective one of a pair of ball bearings **507a**, **507b**. Proximally arranged relative to the proximal pivot housing **503** is a tube housing **523**.

20

Each one of the pair of input bevel gears **505a**, **505b** includes a longitudinally arranged orifice at its proximal end. Arranged proximally relative to the first ball bearing **507a** is a bevel thrust block **509**. The bevel thrust block **509** has a longitudinally-arranged bore therethrough. A distal end of a clamp shaft **527** is configured to extend through a longitudinally-arranged opening of the tube housing **523**, through the longitudinally-arranged bore of the bevel thrust block **509**, through the longitudinally-arranged bore of the ball bearing **507a**, and to engage the longitudinally-arranged orifice at the proximal end of the input bevel gear **505a**. Advantageously, the distal end of a clamp shaft **527** and the longitudinally-arranged orifice at the proximal end of the input bevel gear **505a** are correspondingly sized and shaped such that, when engaged, rotation of the clamp shaft **527** causes rotation of the input bevel gear **505a**.

Also, proximally arranged relative to the second ball bearing **507b** is a bevel thrust block **511**. The outer circumferential surface of the bevel thrust block **511** includes a circular-shaped notch **5111** which is configured to have seated therein an articulation thrust pin **513**. A proximal articulation gear **515** has a central orifice into which the articulation thrust pin **513** is configured to be inserted from below. The bevel thrust block **511** also has a longitudinally-arranged bore there-through. A distal end of a firing shaft **529** is configured to extend through a longitudinally-arranged opening of the tube housing **523**, through the longitudinally-arranged bore of the bevel thrust block **511**, and to engage the longitudinally-arranged orifice at the proximal end of the input bevel gear **505b**. Advantageously, the distal end of a firing shaft **529** and the longitudinally-arranged orifice at the proximal end of the input bevel gear **505b** are correspondingly sized and shaped such that, when engaged, rotation of the firing shaft **529** causes rotation of the input bevel gear **505b**.

The tube housing **503** has a pair of vertically-aligned bores **5031** at its distal end. In addition, the tube housing **503** has a suitably shaped slot at its distal end to receive a portion of the proximal articulation gear **515**. In addition to the articulation thrust pin **513** which is configured to be inserted from below into the central orifice of the proximal articulation gear **515**, the central orifice of the articulation gear **515** is also suitably sized and shaped so as to receive from above a rack gear **519**. The teeth of the rack gear **519** are configured to engage a rack **517**. The rack **517** extends through a corresponding shaped longitudinally-arranged opening in the tube housing **513**. An orifice at the proximal end of the rack **517** is configured to receive a distal end of an articulation shaft **525**, and is maintained in position relative thereto by a clip **521**.

As set forth above, FIG. 4(b) is an exploded perspective view that illustrates an articulation assembly section of the distal assembly, according to the embodiment illustrated in FIG. 3(f). FIG. 4(b) illustrates a firing spring **531** which is configured to engage a firing input bevel gear **533**. The firing input bevel gear **533** is configured to extend through a longitudinally-arranged opening in a cartridge housing coupling **535** and has a bevel gear **5331** at its proximal end. In addition, a clamp screw shaft **537** also extends through a longitudinally-arranged opening in the cartridge housing coupling **535**. Arranged proximally relative to the clamp screw shaft **537** is an outer idler gear **539**. The outer idler gear **539** includes a longitudinally-arranged bore through which a proximal end of the clamp screw shaft **537** is configured to extend. The outer idler gear **539** also includes outer circumferential gear teeth.

FIG. 4(b) also illustrate a combination bevel/spur gear component **541**. The combination bevel/spur gear component **541** is configured to be rotatably mounted at its distal end

21

5411 within a correspondingly-sized and shaped orifice in the cartridge housing coupling **535**. In addition, the combination bevel/spur gear component **541** includes, along an intermediate region thereof, a spur gear **5412** having outer circumferential teeth. The outer circumferential teeth of the outer idler gear **539** are configured to meshingly engage with the outer circumferential teeth of the spur gear **5412** of the combination bevel/spur gear component **541**. Also, the combination bevel/spur gear component **541** includes, at its proximal end, a bevel gear **5413**.

FIG. 4(b) also illustrates a distal pivot housing **543**. The distal pivot housing **543** has a pair of vertically-aligned bores **5431** at its proximal end. Also, the bevel gear **5413** at the distal end of the combination bevel/spur gear component **541**, the outer idler gear **539**, and the bevel gear **5331** at the distal end of the fire input bevel component **533** are each configured to reside within respective longitudinally-arranged orifices of the distal pivot housing **543**. In addition, the distal pivot housing **543** includes a pair of longitudinally arranged orifices, each one of which is configured to receive a respective one of a pair of threaded screws **545a**, **545b**.

The distal pivot housing **543** has a suitably shaped slot at its distal end to receive a portion of distal articulation gear **547**. The distal articulation gear **547** defines a central orifice and outer circumferential gear teeth that extend around at least a portion of the outer circumference of the distal articulation gear **547**. A pair of idler bevel gears **549a**, **549b** are arranged on respective opposite upper and lower surfaces of the distal articulation gear. Each one of the pair of idler bevel gears **549a**, **549b** include a centrally-disposed orifice which is configured to be aligned with the centrally-disposed orifice of the distal articulation gear **547**. A hinge pin **551** is configured to be received within the pair of vertically-aligned bores **5031** at the distal end of the proximal pivot housing **503**, within the pair of vertically-aligned bores **5431** at the proximal end of the distal pivot housing **543**, within the respective centrally-disposed orifices of each one of the pair of idler bevel gears **549a**, **549b**, and within the centrally-disposed orifice of the distal articulation gear **547**.

As set forth above, FIG. 4(c) is an exploded perspective view that illustrates a distal section of the distal assembly, according to the embodiment illustrated in FIG. 3(f). FIG. 4(c) illustrates the first jaw **50** and a second jaw **80**. A proximal portion of the first jaw **50** includes a first slot **552**, which is extends along side surfaces of the proximal portion of the first jaw **50**. Also, the proximal portion of the first jaw **50** includes a second slot **556**, which extends along a top surface of the proximal portion of the first jaw **50**. In addition, a proximal portion of the second jaw **80** is sized and shaped such that the proximal portion of the second jaw may fit within the second slot **556** of the first jaw **50**, such that the proximal portion of the second jaw **80** resides within the proximal portion of the first jaw **50**. In addition, the proximal portion of the second jaw includes a slot **554**.

An inner shaft **555** is configured to fit within, and to be moveable in generally distal and proximal directions relative to, the first slot **552** of the first jaw **50** and the slot **554** of the second jaw **80**. The inner shaft **555** includes a threaded bore that extends radially therethrough from a first circumferential surface to an opposite circumferential surface. A clamp screw **559** is configured to be received within a longitudinally-arranged orifice of the proximal end of the second jaw **80**. The threaded bore of the inner shaft **555** is configured to receive a threaded distal end of the clamping screw **559**. The clamping screw **559** also includes at its proximal end a longitudinally-

22

arranged orifice, which is suitably sized and shaped so as to receive a correspondingly-sized and shaped distal end of the clamp screw shaft **537**.

FIG. 4(c) also illustrates a firing shaft **557**. A distal end of the firing shaft **557** includes a longitudinally-arranged orifice, which is suitably sized and shaped so as to receive a correspondingly-sized and shaped proximal end of, e.g., a threaded drive shaft (not shown) of the cutting and stapling element **104** that extends from a proximal end to a distal end of the second jaw **80**. A proximal end of the firing shaft **557** has a smaller diameter than the distal end thereof, and is configured to be received longitudinally within the spring **531**. Also, the proximal end of the firing shaft **557** has a cross-section size and shape that is suitable to be received within a correspondingly-sized and shaped, longitudinally-arranged bore at the distal end of the fire input bevel **533**. A pair of nuts **563a**, **563b** are configured to engage respective ones of the threaded screws **545a**, **545b**, each of which extends through a respective one of the pair of longitudinally arranged orifices of the distal pivot housing **543** and through a respective one of a pair of longitudinally arranged orifices of the second jaw **80**.

FIG. 4(d) is a side perspective view, partially in section, of the distal assembly of the surgical device **11**, as assembled, that shows additional details of the region at which the surgical device **11** is configured to articulate, according to the embodiment illustrated in FIG. 3(f). For example, FIG. 4(d) illustrates the proximal pivot housing **503** (in phantom) connected to the distal pivot housing **543** (also in phantom) by hinge pin **551** extending through the vertically-aligned orifices **5031** of the proximal pivot housing **503** and the vertically-aligned orifices **5431** of the distal pivot housing **543**. The hinge pin **551** is also inserted through the central orifice of the distal articulation gear **547**, and through the centrally-disposed orifices of the pair of idler bevel gears **549a**, **549b** that are arranged on respective opposite upper and lower surfaces of the distal articulation gear **547**.

The clamp shaft **527** extends distally and extends through a longitudinally-arranged opening of the tube housing **523**, through the longitudinally-arranged bores of the bevel thrust block **509** and ball bearing **507a**, and engages the longitudinally-arranged orifice at the proximal end of the input bevel gear **505a**. The gear teeth of the input bevel gear **505a** are meshingly engaged with the gear teeth of the upper idler bevel gear **549a**. Also meshingly engaged with the gear teeth of the upper idler bevel gear **549a** are the gear teeth of the bevel gear **5413** of the combination bevel/spur gear component **541**. The combination bevel/spur gear component **541** is rotatably mounted at its distal end **5411**. In addition, the outer circumferential teeth of the spur gear **5412** of the combination bevel/spur gear component **541** are meshingly engaged with the outer circumferential teeth of the outer idler gear **539** which is mounted on the clamp screw shaft **537**.

The fire shaft **529** extends distally and extends through a longitudinally-arranged opening of the tube housing **523**, through the longitudinally-arranged bores of the bevel thrust block **511** and ball bearing **507b**, and engages the longitudinally-arranged orifice at the proximal end of the input bevel gear **505b**. The gear teeth of the input bevel gear **505b** are meshingly engaged with the gear teeth of the lower idler bevel gear **549b**. Also meshingly engaged with the gear teeth of the lower idler bevel gear **549b** are the gear teeth of the bevel gear **5331** of the firing input bevel gear **533**. The firing input bevel gear **533** extends distally to the firing shaft **557**.

The articulation shaft **525** also extends distally and extends through a longitudinally-arranged opening of the tube housing **523**. Mounted to the distal end of the articulation shaft **525** by clip **521** is rack **537**, the teeth of which are engaged with

23

the outer circumferential teeth of the rack gear **519**. The rack gear **519** is positioned on an upper surface of the proximal articulation gear **515**, and is rotatably mounted on the articulation thrust pin **513**. The outer circumferential gear teeth of the proximal articulation gear **515** are meshingly engaged with the outer circumferential gear teeth of the distal articulation gear **547**. The distal articulation gear **547** is rotationally fixed relative to the distal pivot housing **543**.

As set forth above, the surgical device **11** may also include a cutting and stapling element **104**. In an embodiment, the staple and cutting element **104** is a staple cartridge. FIG. 4(e) is an exploded view of a replaceable staple cartridge **2600**. The replaceable staple cartridge **2600** is one type of stapling/cutting arrangement that may be employed as the cutting and stapling element **104** in the example embodiment of the present invention illustrated in, e.g., FIGS. 3(a) to 3(e). The replaceable staple cartridge **2600** includes a staple tray **2604**. The staple tray **2604** has a slot **2604i** at its proximal end **2604d** in which the memory module **6041** is retained by a memory module retainer **6042**. The memory module **6041** may store information as described, for example, in U.S. patent application Ser. No. 09/723,715, filed on Nov. 28, 2000, now issued as U.S. Pat. No. 6,793,652 on Sep. 21, 2004, U.S. patent application Ser. No. 09/836,781, filed on Apr. 17, 2001, U.S. patent application Ser. No. 09/887,789, filed on Jun. 22, 2001 and U.S. patent application Ser. No. 10/099,634, filed on Mar. 15, 2002, each of which is expressly incorporated herein by reference in its entirety. A wedge driver **2605** is configured to be rotatably disposed through a central channel **2604e** of the staple tray **2604**. Specifically, the wedge driver **2605** has a distal end **2605a** that is configured to be rotatably mounted within a distal orifice **2604a** of the staple tray **2604**. The wedge driver **2605** also includes an externally threaded region **2605b**, a non-threaded portion **2605c** that rotatably extends through a proximal orifice **2604b** in the proximal end **2604b** of the staple tray **2604**, and a proximally-facing opening **2605d** at its proximal-most end for receiving the distal end of the clamp screw **559**. The proximally-facing opening **2605d** and the distal end of the clamp screw **559** are adapted for non-rotatable coupling relative to each other when the distal end of the clamp screw **559** is received, e.g., inserted, within the proximally-facing opening **2605d**.

The replaceable staple cartridge **2600** also includes a wedge **2603** having an internally threaded bore **2603a**. The externally threaded region **2605b** of the wedge driver **2605** is configured to extend through the internally threaded bore **2603a** of the wedge **2603**. The threads of the internally threaded bore **2603a** of the wedge **2603** match the threads of the externally threaded region **2605b** of the wedge driver **2605**. As is discussed further below, upon rotation of the wedge driver **2605**, the wedge **2603** is moved between the distal end **2604c** of the staple tray **2604** and the proximal end **2604d** of the staple tray **2604** through a central channel **2604e**.

The staple tray **2604** also includes a plurality of vertically-disposed slots **2604f** in opposing walls **2604g** of the central channel **2604e**. On each side of the central channel **2604e**, a staple pusher **2607** is configured to be slideably disposed within the slots **2604f**. More specifically, each of the staple pushers **2607** has a top surface **2607a** running longitudinally between two rows **2607b** of staple pushing fingers **2607c**. The staple pushing fingers **2607c** are configured such that each staple pushing finger **2607c** in the row **2607b** that abuts the wall **2604g** of the staple tray **2604** is retained within a corresponding slot **2604f** of the wall **2604g** so as to be vertically slideable therein. The staple pushing fingers **2607c** are positioned over slots **2604h** in the staple tray **2604**. The slots

24

2604h in the staple tray **2604** house a plurality of fasteners, e.g., staples **2606**. Each of the staples **2606** includes a butt **2606a** and a pair of prongs **2606b**.

The wedge **2603** also includes a pair of sloped edges **2603b** that slideably engage respective top surfaces **2607a** of the staple pushers **2607**. When the wedge **2603** is moved from the distal end **2604c** to the proximal end **2604d** of the staple tray **2604** through the central channel **2604e**, the pair of sloped edges **2603b** of the wedge **2603** is configured to slideably engage the respective top surfaces **2607a** of the staple pushers **2607** in order to successively push the staple pushing fingers **2607c** of the staple pushers **2607** into, and thus the staples **2606** out of, the slots **2604h** in the staple tray **2604**. A cartridge top **2611** is configured to fit over the central channel **2604a** of the staple tray **2604**, while a staple retainer **2610** is configured to cover the clamping surface **106** of the staple tray **2604**. Additional features, e.g., a blade **51**, of the staple cartridge **2600** are described below in connection with FIG. 4(f), these features being described during operation of the surgical device **11**.

FIG. 4(f) is a bottom view of the first jaw **50**. The first jaw **50** includes an anvil member **2700** having a longitudinally-disposed slot **2701** that extends from a distal end to a proximal end of the anvil member **2700**. The slot **2701** is aligned with the blade **51** of the second jaw **80** so that the blade **51** extends into and travels along the slot **2701** when the blade is moved from the distal end **80a** to the proximal end **80b** of the second jaw **80**. The anvil member **2700** also includes a plurality of rows **2702** of staple guides **2703**. The staple guides **2703** are configured to receive the prongs **2606b** of the staples **2606** and to bend the prongs **2606b** so as to close the staples **2606**. When the surgical device **11** is in the closed position, the rows **2702** of the staple guides **2703** align with the slots **2604h** of the staple tray **2604** in the second jaw **80**.

As set forth above, the surgical device **11** of the present invention, in accordance with various embodiments thereof, may be configured to select and then perform various different functions during the course of a surgical procedure. Set forth below is an example procedure in which the surgical device **11** may be employed.

In operation, the jaw portion **11a** is maintained in an initial position in which it is axially aligned with the shaft portion **11b**, such as the position shown in FIG. 3(b). In this position, the surgical device **11** may be inserted, e.g., through a trocar, into a surgical site. Depending on the position of the incision and the tissue to be clamped, stapled and cut, the user may then operate the surgical device **11**.

Once the surgical device **11** has been inserted within a patient, the shaft portion **11b** may be rotated, e.g., the shaft portion **11b** may be rotated relative to, and about the longitudinal axis D of, the handle **1103**. Of course, it should be recognized that, in the example embodiment described herein, rotation of the shaft portion **11b** relative to the handle **1103** also causes rotation of the jaw portion **11a** disposed distally relative to the shaft portion **11b**. In other embodiments, rotation may be achieved by the jaw portion **11a** rotating relative to and about a longitudinal axis of the shaft portion **11b**, or, in an embodiment in which the jaw portion **11a** is coupled directly to the handle **1103**, by the jaw portion **11a** rotating relative to and about a longitudinal axis of the handle **1103**. For the purposes of this application, the "shaft portion" is intended to refer to any portion of the component of the surgical device that is located distally relative to a handle.

In order to perform this first function, the surgical device **11** may be operated such that the function selector module **1110** is moved to a first functional position. As set forth above, in

25

this first functional position, the function selector module **1110** causes engagement of the second rotatable drive shaft **1110b** with a rotation driver **202**. FIG. **5(a)** is a side perspective view, partially in section, of the handle **1103** of the surgical device. In particular, FIG. **5(a)** illustrates some of the components of the handle **1103** that form the rotation driver **202** and that function to rotate a shaft portion of the surgical device **11** relative to the handle **1103** about the longitudinal axis of the handle **1103**, according to the embodiment illustrated in FIGS. **3(a)** through **3(e)**. FIG. **5(a)** illustrates some of these rotation driver **202** components in bold.

Referring now to FIG. **5(a)**, the first rotatable drive shaft **1110a** is caused to rotate, e.g., such as by motor **96** (shown in FIG. **2(b)**) in, e.g., a counter-clockwise direction (for the sake of simplicity, all references herein to a rotational direction, e.g., clockwise or counterclockwise, refer to a view from the proximal end of the surgical device towards the distal end of the surgical device **11**, unless otherwise noted; furthermore, it should be recognized that, while the disclosure hereinbelow includes, for each of the components of the surgical device **11**, various references to rotational directions in order to perform a specific function, these directions are merely exemplary because certain components may be differently configured, e.g., threaded portions may have a right-hand thread as opposed to a left-hand thread, etc., such that the rotational directions set forth herein may be reversed in order to perform the same below-described functions). Since the longitudinally-arranged bore of the first rotatable drive shaft **1110a** and the proximal end of a selector shaft **601** are correspondingly sized and shaped, rotation of the first rotatable drive shaft **1110a** in a counter-clockwise direction causes rotation of the selector shaft **601** in a counter-clockwise direction. By virtue of the threaded engagement of the threaded portion **607** of the selector shaft **601** within the threaded bore of the function selector block **609**, rotation of the selector shaft **601** in a counter-clockwise direction causes the function selector block **609** to move to a distal-most, e.g., first, position, in which specific gears of the handle **1103** are engaged with each other. It should be recognized that, while the function selector block **609** may be moved to this distal-most, e.g., first, position by rotation of the selector shaft **601**, in various other embodiments, the surgical device **11** may be configured such that the function selector block **609** is initially in this first position.

Once the function selector block **609** is moved to the first position, the second rotatable drive shaft **1110b** may be caused to rotate, e.g., in a counter-clockwise direction, such as by motor **100** (shown in FIG. **2(b)**). Since the longitudinally-arranged bore of the second rotatable drive shaft **1110b** and the proximal end of the function shaft **611** are correspondingly sized and shaped, rotation of the second rotatable drive shaft **1110b** in a counter-clockwise direction causes rotation of the function shaft **611** in a counter-clockwise direction. The input spur gear **619** of the second rotatable drive shaft **1110b** also rotates. Due to the engagement of the outer circumferential gear teeth **6191** of the input spur gear **619** with the outer circumferential gear teeth **6231** of the rotation spur gear **623**, rotation of the input spur gear **619** in a counter-clockwise direction causes rotation of the rotation spur gear **623** in a clockwise direction.

When the function selector block **609** is in the first position, the rotation spur gear **623** and the rotation spur gear **631** are engaged with the gear shaft **621** such that rotation of the rotation spur gear **623** in a clockwise direction causes rotation of the gear shaft **621** in a clockwise direction and also rotation of the rotation spur gear **631** in a clockwise direction. By virtue of the meshing engagement of the outer circumferen-

26

tial gear teeth **6311** of the rotation spur gear **631** with the outer circumferential gear teeth **6391** of the rotation spur gear **639**, rotation of the rotation spur gear **631** in a clockwise direction causes rotation of the rotation spur gear **639** in a counter-clockwise direction.

Rotation of the rotation spur gear **639**, which is mounted at an end of the rotation gear shaft **633**, in a counter-clockwise direction causes rotation of the rotation gear shaft **633** in a counter-clockwise direction and rotation of the rotation worm gear **641**, which is also mounted thereon, in a counter-clockwise direction. By virtue of the engagement of outer circumferential worm gear teeth **6411** of the rotation worm gear **641** with the outer circumferential gear teeth **6431** of the rotation gear **643**, rotation of the rotation worm gear **641** in a counter-clockwise direction causes rotation of the rotation gear **643** in a clockwise direction (as viewed when looking into the page) about a pivot axis that is perpendicular to a longitudinal axis of the rotation gear shaft **633**. Likewise, rotation of the rotation gear **643** in a clockwise direction causes rotation of the rotation miter gear **644**, that is mounted thereon, in a clockwise direction. The miter gear teeth **6441** of the rotation miter gear **644** engage the miter gear teeth **6691** of the rotation miter gear **669**, such that rotation of the rotation miter gear **644** in a clockwise direction causes rotation of the rotation miter gear **669** in a counter-clockwise direction.

The rotation miter gear **669** is mounted on the second rotation gear shaft **665**, such that rotation of the rotation miter gear **669** in a counter-clockwise direction causes rotation of the second rotation gear shaft **665** in a counter-clockwise direction and of the rotation spur gear **673** in a counter-clockwise direction. By virtue of the meshing engagement of the outer circumferential gear teeth **6731** of the rotation spur gear **673** with the outer circumferential gear teeth **6791** of the rotating tube spur gear **679**, rotation of the rotation spur gear **673** in a counter-clockwise direction causes rotation of the rotating tube spur gear **679** in a clockwise direction and also rotation of the rotating tube **677** mounted thereto in a clockwise direction. The rotation of the rotating tube **677** within a mouth **675** at the distal-most end of the handle **1103** provides the first above-described function of moving, e.g., rotating, the shaft portion **11b** about a longitudinal axis of the handle **1103**. Of course, the movement, e.g., rotation, in the opposite direction may also be accomplished by reversing the direction in which the above-described gears are caused to rotate.

FIG. **6(a)** is a side perspective view, partially in section, of another section of the distal portion of the surgical device **11**. In particular, FIG. **6(a)** illustrates the rotation of the shaft portion **11b** of the surgical device **11** about the longitudinal axis of the handle **1103**, according to an embodiment of the present invention.

Once the shaft portion **11b** has been rotated relative to the handle **1103**, the surgical device **11** may be employed to move the jaw portion **11a** relative to the shaft portion **11b**, e.g., to pivot the jaw portion **11a** about axis B relative to the shaft portion **11b**. In order to perform this second function, the surgical device **11** may be operated such that the function selector module **1110** is moved to a second functional position. As set forth above, in this second functional position, the function selector module **1110** causes engagement of the second rotatable drive shaft **1110b** with an articulation driver **201**. FIG. **5(b)** is a side perspective view, partially in section, of the handle **1103** of the surgical device. In particular, FIG. **5(b)** illustrates some of the components of the handle **1103** that form the articulation driver **201** and that function to move, e.g., articulate, the jaw portion **11a** relative to the shaft portion **11b**, according to the embodiment illustrated in FIGS.

3(a) through 3(e). FIG. 5(b) illustrates some of these articulation driver **201** components in bold.

Referring to FIG. 5(b), the first rotatable drive shaft **1110a** is again caused to rotate, e.g., in a clockwise direction, such as by motor **96** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the first rotatable drive shaft **1110a** and the proximal end of a selector shaft **601** are correspondingly sized and shaped, rotation of the first rotatable drive shaft **1110a** in a clockwise direction causes rotation of the selector shaft **601** in a clockwise direction. By virtue of the threaded engagement of the threaded portion **607** of the selector shaft **601** within the threaded bore of the function selector block **609**, rotation of the selector shaft **601** causes the function selector block **609** to move proximally to, e.g., a second position, in which specific gears of the handle **1103** are engaged with each other.

Once the function selector block **609** is moved to the second position, the second rotatable drive shaft **1110b** is caused to rotate, e.g., in a counter-clockwise direction, such as by motor **100** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the second rotatable drive shaft **1110b** and the proximal end of the function shaft **611** are correspondingly sized and shaped, rotation of the second rotatable drive shaft **1110b** in a counter-clockwise direction causes rotation of the function shaft **611** in a counter-clockwise direction. The first spur gear **617** of the second rotatable drive shaft **1110b** is also caused to rotate in a counter-clockwise direction. Due to the engagement of the outer circumferential gear teeth **6191** of the input spur gear **619** with the outer circumferential gear teeth **6231** of the articulation spur gear **623**, rotation of the input spur gear **619** in a counter-clockwise direction causes rotation of the articulation spur gear **623** in a clockwise direction.

When the function selector block **609** is in the second position, the rotation spur gear **623** and the articulation spur gear **629** are engaged with the gear shaft **621** such that rotation of the rotation spur gear **623** in a clockwise direction causes rotation of the gear shaft **621** in a clockwise direction and also rotation of the articulation spur gear **629** in a clockwise direction. By virtue of the meshing engagement of the outer circumferential gear teeth **6291** of the articulation spur gear **629** with the outer circumferential gear teeth **6871** of the articulation spur gear **687**, rotation of the articulation spur gear **629** in a clockwise direction causes rotation of the articulation spur gear **687** in a counter-clockwise direction.

Rotation of the articulation spur gear **687**, which is mounted at an end of the articulation gear shaft **685**, in a counter-clockwise direction causes rotation of the articulation gear shaft **685** in a counter-clockwise direction and of the articulation worm gear **689**, which is also mounted thereon, in a counter-clockwise direction. By virtue of the engagement of outer circumferential worm gear teeth **6891** of the articulation worm gear **689** with the outer circumferential gear teeth **6911** of the articulation gear **691**, rotation of the articulation worm gear **689** in a counter-clockwise direction causes rotation of the articulation gear **691** in a counter-clockwise direction (when viewed into the page) about a pivot axis that is perpendicular to a longitudinal axis of the articulation gear shaft **685**. Likewise, rotation of the articulation gear **691** in a counter-clockwise direction causes rotation of the articulation miter gear **692**, that is mounted thereon, in a counter-clockwise direction. The miter gear teeth **6921** of the articulation miter gear **692** engage the miter gear teeth **6961** of the articulation miter gear **696**, such that rotation of the articulation miter gear **692** in a counter-clockwise direction causes rotation of the articulation miter gear **696** in a counter-clockwise direction.

The articulation miter gear **696** is mounted on the second articulation gear shaft **693**. By virtue of the threaded engagement between the threaded rod portion **695** of the second articulation gear shaft **693** and the interior threaded bore of the articulation miter gear **696**, rotation of the articulation miter gear **696** in a counter-clockwise direction causes the second articulation gear shaft **693** to move, e.g., distally (depending on the direction of threads on the second articulation gear shaft **693**).

FIG. 6(b) is a side perspective view, partially in section, of another section of the distal portion of the surgical device **11**. In particular, FIG. 6(b) illustrates additional components of the surgical device **11** that function to move, e.g., articulate, the jaw portion **11a** relative to the shaft portion **11b**, according to the embodiment illustrated in FIGS. 3(f) and 4(d). FIG. 6(b) illustrates some of these articulation driver **201** components in bold.

As shown in FIG. 6(b), movement of the articulation shaft **525** distally causes the rack **517** to also move distally. By virtue of the engagement of the teeth of the rack **517** with the teeth of the rack gear **519**, distal movement of the rack **517** causes the rack gear **519**, and the proximal articulation gear **515**, to rotate in a clockwise direction (when viewed from above). Also, by virtue of the engagement of the outer circumferential teeth of the proximal articulation gear **515** with the outer circumferential teeth of the distal articulation gear **547**, rotation of the proximal articulation gear **515** in a clockwise direction causes rotation of the distal articulation gear **547** in a counter-clockwise direction. Since the distal articulation gear **547** is rotationally fixed relative to the distal pivot housing **543**, rotation of the distal articulation gear **547** in a counter-clockwise direction causes the jaw portion **11a** to move, e.g., articulate, in a counter-clockwise direction (when viewed from above) relative to the shaft portion **11b** about the hinge pin **551**, which defines in this example embodiment the axis B shown in FIG. 2(b). Of course, the movement, e.g., articulation, in the opposite direction may also be accomplished by reversing the direction in which the above-described gears are caused to rotate.

Once the jaw portion **11a** has been articulated about axis B relative to the shaft portion **11b**, the jaws **50**, **80** may be moved, e.g., opened, so as to enable a section of tissue to be disposed therebetween. In order to perform this third function, the surgical device **11** may be operated such that the function selector module **1110** is moved to a third functional position. As set forth above, in this third functional position, the function selector module **1110** causes engagement of the second rotatable drive shaft **1110b** with a clamping driver **88**. FIG. 5(c) is a side perspective view, partially in section, of the handle **1103** of the surgical device **11**. In particular, FIG. 5(c) illustrates some of the components of the handle **1103** that form the clamping driver **88** and that function to move, e.g., to open, the first jaw **50** relative to the second jaw **80**, according to the embodiment illustrated in FIGS. 3(a) through 3(e). FIG. 5(c) illustrates some of these clamping driver **88** components in bold.

Referring to FIG. 5(c), the first rotatable drive shaft **1110a** is again caused to rotate, e.g., in a clockwise direction, such as by motor **96** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the first rotatable drive shaft **1110a** and the proximal end of a selector shaft **601** are correspondingly sized and shaped, rotation of the first rotatable drive shaft **1110a** in a clockwise direction causes rotation of the selector shaft **601** in a clockwise direction. By virtue of the threaded engagement of the threaded portion **607** of the selector shaft **601** within the threaded bore of the function selector block **609**, rotation of the selector shaft **601** in a clockwise direction

29

causes the function selector block **609** to move proximally to, e.g., a third position, in which specific gears of the handle **1103** are engaged with each other.

Once the function selector block **609** is moved to the third position, the second rotatable drive shaft **1110b** is caused to rotate, e.g., in a counter-clockwise direction, such as by motor **100** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the second rotatable drive shaft **1110b** and the proximal end of the function shaft **611** are correspondingly sized and shaped, rotation of the second rotatable drive shaft **1110b** in a counter-clockwise direction causes rotation of the function shaft **611** in a counter-clockwise direction. The input spur gear **619** of the second rotatable drive shaft **1110b** is also caused to rotate in a counter-clockwise direction. Due to the engagement of the outer circumferential gear teeth **6191** of the input spur gear **619** with the outer circumferential gear teeth **6231** of the rotation spur gear **623**, rotation of the input spur gear **619** in a counter-clockwise direction causes rotation of the rotation spur gear **623** in a clockwise direction.

When the function selector block **609** is in the third position, the rotation spur gear **623** and the clamping spur gear **627** are engaged with the gear shaft **621** such that rotation of the rotation spur gear **623** in a clockwise direction causes rotation of the gear shaft **621** in a clockwise direction and also rotation of the clamping spur gear **627** in a clockwise direction. By virtue of the meshing engagement of the outer circumferential gear teeth **6271** of the clamping spur gear **627** with the outer circumferential gear teeth **6551** of the clamping spur gear **655**, rotation of the clamping spur gear **627** in a clockwise direction causes rotation of the clamping spur gear **655** in a counter-clockwise direction. Clamping spur gear **655** is mounted at an end of the clamping gear shaft **651** that has the first clamping miter gear **657** mounted at its opposite end, such that rotation of the clamping spur gear **655** in a counter-clockwise direction also causes rotation of the clamping gear shaft **651** in a counter-clockwise direction and the first clamping miter gear **657** in a counter-clockwise direction.

The miter gear teeth **6571** of the first clamping miter gear **657** engage the miter gear teeth **6591** of the second clamping miter gear **659**, such that rotation of the first clamping miter gear **657** in a counter-clockwise direction causes rotation of the second clamping miter gear **659** in a counter-clockwise direction (when viewed into the page) about an axis that is perpendicular to the longitudinal axis of the clamping gear shaft **651**. Likewise, the miter gear teeth **6591** of the second clamping miter gear **659** engage the miter gear teeth **6611** of the third clamping miter gear **661**, such that rotation of the second clamping miter gear **659** in a counter-clockwise direction causes rotation of the third clamping miter gear **661** in a clockwise direction. The third clamping miter gear **661** is mounted at the proximal end of the second clamping gear shaft **681** such that rotation of the third clamping miter gear **661** in a clockwise direction causes rotation of the second clamping gear shaft **681** in a clockwise direction.

FIG. 6(c) is a side perspective view, partially in section, of another section of the distal portion of the surgical device **11**. In particular, FIG. 6(c) illustrates additional components of the surgical device **11** that function to move, e.g., open, the first jaw **50** relative to the second jaw **80**, according to the embodiment illustrated in FIGS. 3(f) and 4(d). FIG. 6(c) illustrates some of these clamping driver **88** components in bold.

As set forth above, the second clamping gear shaft **681** extends distally through the rotating tube **677** to eventually form the clamp shaft **527**. The rotation of the clamp shaft **527** in a clockwise direction causes rotation of the input bevel gear **505a** in a clockwise direction. By virtue of the meshing

30

engagement of the gear teeth of the input bevel gear **505a** with the gear teeth of the upper idler bevel gear **549a**, rotation of the input bevel gear **505a** in a clockwise direction about the longitudinal axis of the clamping shaft **527** causes rotation of the upper idler bevel gear **549a** in a clockwise direction (when viewed from above). Likewise, by virtue of the meshing engagement of the gear teeth of the upper idler bevel gear **549a** with the gear teeth of the bevel gear **5413** of the combination bevel/spur gear component **541**, rotation of the upper idler bevel gear **549a** in a clockwise direction about the longitudinal axis of the hinge pin **551** causes rotation of the bevel gear **5413** of the combination bevel/spur gear component **541** in a counter-clockwise direction, along with rotation of the spur gear mounted on the combination bevel/spur gear component **541** in a counter-clockwise direction. Since the outer circumferential teeth of the spur gear of the combination bevel/spur gear component **541** are meshingly engaged with the outer circumferential teeth of the outer idler gear **539**, rotation of the spur gear of the combination bevel/spur gear component **541** in a counter-clockwise direction causes rotation of the outer idler gear **539** in a clockwise direction and rotation of the clamp screw shaft **537**, on which it is mounted, in a counter-clockwise direction.

Referring now to FIG. 4(c), the clamp screw **559**, which is mounted on the distal end of the clamp screw shaft **537**, is also caused to turn in a counter-clockwise direction. The inner shaft **555** is threadedly engaged with the outer threads of the clamp screw **559**, such that rotation of the clamp screw **559** in a counter-clockwise direction causes the inner shaft **555** to move in a proximal direction within the slots **552** and **554** of the first and second jaws **50** and **80**, respectively. This proximal movement of the inner shaft **555** allows the first and second jaws to move, e.g., open, relative to each other. Additional details of this clamping arrangement may be found, for example, in U.S. patent application Ser. No. 11/191,851, entitled "Surgical Device," filed Jul. 27, 2005, the disclosure of which is hereby incorporated by reference in its entirety.

Once the first and second jaws **50**, **80** have been opened to a desired position relative to each other, and once a section of tissue desired to be operated on is satisfactorily positioned between the first and second jaws **50**, **80** of the surgical device **11**, the first and second jaws **50**, **80** are closed so as to clamp the section of tissue therebetween.

In order to close the first and second jaws **50**, **80** relative to each other, the function selector module **1110** may remain in the third functional position. As set forth above, in this third functional position, the function selector module **1110** causes engagement of the second rotatable drive shaft **1110b** with the clamping driver **88**.

Referring to FIG. 5(c), with the function selector block **609** in the third position, the second rotatable drive shaft **1110b** is caused to rotate, e.g., in a clockwise direction, such as by motor **100** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the second rotatable drive shaft **1110b** and the proximal end of the function shaft **611** are correspondingly sized and shaped, rotation of the second rotatable drive shaft **1110b** in a clockwise direction causes rotation of the function shaft **611** in a clockwise direction. The input spur gear **619** of the second rotatable drive shaft **1110b** is also caused to rotate in a clockwise direction. Due to the engagement of the outer circumferential gear teeth **6191** of the input spur gear **619** with the outer circumferential gear teeth **6231** of the rotation spur gear **623**, rotation of the input spur gear **619** in a clockwise direction causes rotation of the rotation spur gear **623** in a counter-clockwise direction.

Again, when the function selector block **609** is in the third position, the rotation spur gear **623** and the clamping spur

31

gear **627** are engaged with the gear shaft **621** such that rotation of the rotation spur gear **623** in a counter-clockwise direction causes rotation of the gear shaft **621** in a counter-clockwise direction and also rotation of the clamping spur gear **627** in a counter-clockwise direction. By virtue of the meshing engagement of the outer circumferential gear teeth **6271** of the clamping spur gear **627** with the outer circumferential gear teeth **6551** of the clamping spur gear **655**, rotation of the clamping spur gear **627** in a counter-clockwise direction causes rotation of the clamping spur gear **655** in a clockwise direction. Clamping spur gear **655** is mounted at an end of the clamping gear shaft **651**, that has the first clamping miter gear **657** mounted at its opposite end, such that rotation of the clamping spur gear **655** in a clockwise direction also causes rotation of the clamping gear shaft **651** in a clockwise direction and the first clamping miter gear **657** in a clockwise direction.

The miter gear teeth **6571** of the first clamping miter gear **657** engage the miter gear teeth **6591** of the second clamping miter gear **659**, such that rotation of the first clamping miter gear **657** in a clockwise direction causes rotation of the second clamping miter gear **659** in a clockwise direction (when viewed into the page) about an axis that is perpendicular to the longitudinal axis of the clamping gear shaft **651**. Likewise, the miter gear teeth **6591** of the second clamping miter gear **659** engage the miter gear teeth **6611** of the third clamping miter gear **661**, such that rotation of the second clamping miter gear **659** in a clockwise direction causes rotation of the third clamping miter gear **661** in a counter-clockwise direction. The third clamping miter gear **661** is mounted at the proximal end of the second clamping gear shaft **681** such that rotation of the third clamping miter gear **661** in a counter-clockwise direction causes rotation of the second clamping gear shaft **681** in a counter-clockwise direction.

Referring next to FIG. 6(c), the rotation of the clamp shaft **527** in a counter-clockwise direction causes rotation of the input bevel gear **505a** in a counter-clockwise direction. By virtue of the meshing engagement of the gear teeth of the input bevel gear **505a** with the gear teeth of the upper idler bevel gear **549a**, rotation of the input bevel gear **505a** in a counter-clockwise direction about the longitudinal axis of the clamping shaft **527** causes rotation of the upper idler bevel gear **549a** in a counter-clockwise direction (when viewed from above). Likewise, by virtue of the meshing engagement of the gear teeth of the upper idler bevel gear **549a** with the gear teeth of the bevel gear **5413** of the combination bevel/spur gear component **541**, rotation of the upper idler bevel gear **549a** in a counter-clockwise direction about the longitudinal axis of the hinge pin **551** causes rotation of the bevel gear **5413** of the combination bevel/spur gear component **541** in a clockwise direction, along with rotation of the spur gear mounted on the combination bevel/spur gear component **541** in a clockwise direction. Since the outer circumferential teeth of the spur gear of the combination bevel/spur gear component **541** are meshingly engaged with the outer circumferential teeth of the outer idler gear **539**, rotation of the spur gear of the combination bevel/spur gear component **541** in a clockwise direction causes rotation of the outer idler gear **539** in a counter-clockwise direction and of the clamp screw shaft **537**, on which it is mounted, in a counter-clockwise direction.

Referring now to FIG. 4(c), the clamp screw **559**, which is mounted on the distal end of the clamp screw shaft **537**, is also caused to turn in a counter-clockwise direction. The inner shaft **555** is threadedly engaged with the outer threads of the clamp screw **559**, such that rotation of the clamp screw **559** in a counter-clockwise direction causes the inner shaft **555** to move in a distal direction within the slots **552** and **554** of the

32

first and second jaws **50** and **80**, respectively. This distal movement of the inner shaft **555** allows the first and second jaws **50**, **80** to move, e.g., close, relative to each other, thereby clamping the section of tissue between the first and second jaws **50**, **80**.

Once a section of tissue has been clamped between the first and second jaws **50**, **80**, the section of tissue may be cut and/or stapled. It should be recognized that, while the present invention is illustrated as using both cutting and stapling elements, the surgical device **11** may employ only one such element, or else may employ a different type of surgical instrument.

Before the surgical device **11** is inserted into a patient's body, a staple cartridge **578** is provided within the second jaw **80**. In an embodiment, the surgical device **11** is a single-use device, in which the staple cartridge is integral to the second jaw **80**. Alternatively, the surgical device **11** may have a replaceable staple cartridge, e.g., replaceable staple cartridge **600** as illustrated in FIG. 4(e), thereby permitting the surgical device **11** to be used numerous times with different staple cartridges. In this embodiment, if the surgical device **11** is being used for the first time, the staple cartridge **600** may be pre-installed during manufacture and assembly of the surgical device **11**, or else may be installed by the user just prior to using the surgical device **11**. If the surgical device **11** is being used for the second or more time, the staple cartridge **600** may be installed by the user just prior to using the surgical device **11**. When the staple cartridge **600** is inserted into the second jaw **80**, the distal end of the firing shaft **557** is received within the proximally-facing opening **605d** of the wedge driver **605**.

To illustrate the cutting/stapling operation of the surgical device **11**, reference is first made to FIG. 5(d). With the staple cartridge **600** installed within the second jaw **80** of the surgical device **11**, the surgical device **11** may be operated such that the function selector module **1110** is moved to a fourth functional position. As set forth above, in this fourth functional position, the function selector module **1110** causes engagement of the second rotatable drive shaft **1110b** with the firing driver **98**. FIG. 5(d) is a side perspective view, partially in section, of the handle **1103** of the surgical device **11**. In particular, FIG. 5(d) illustrates some of the components of the handle **1103** that form the firing driver **98** and that function to move a cutting and/or stapling element, e.g., to drive a staple pushing element and/or cutting blade through a section of tissue, according to the embodiment illustrated in FIGS. 3(a) through 3(e). FIG. 5(d) illustrates some of these firing driver **98** components in bold.

Referring to FIG. 5(d), the first rotatable drive shaft **1110a** is again caused to rotate, e.g., in a clockwise direction such as by motor **96** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the first rotatable drive shaft **1110a** and the proximal end of a selector shaft **601** are correspondingly sized and shaped, rotation of the first rotatable drive shaft **1110a** in a clockwise direction causes rotation of the selector shaft **601** in a clockwise direction. By virtue of the threaded engagement of the threaded portion **607** of the selector shaft **601** within the threaded bore of the function selector block **609**, rotation of the selector shaft **601** in a clockwise direction causes the function selector block **609** to move proximally to, e.g., a fourth position, in which specific gears of the handle **1103** are engaged with each other.

Once the function selector block **609** is moved to the fourth position, the second rotatable drive shaft **1110b** is caused to rotate, e.g., in a counter-clockwise direction, such as by motor **100** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the second rotatable drive shaft **1110b** and the proximal end of the function shaft **611** are correspondingly sized and shaped, rotation of the second rotatable drive shaft **1110b**

in a counter-clockwise direction causes rotation of the function shaft **611** in a counter-clockwise direction. The input spur gear **619** and the firing spur gear **617** of the second rotatable drive shaft **1110b** are also caused to rotate in a counter-clockwise direction. Due to the engagement of the outer circumferential gear teeth **6171** of the fire spur gear **617** with the outer circumferential gear teeth **6251** of the fire spur gear **625**, rotation of the fire spur gear **617** in a counter-clockwise direction causes rotation of the fire spur gear **625** in a clockwise direction. Likewise, due to the engagement of the outer circumferential gear teeth **6191** of the input spur gear **619** with the outer circumferential gear teeth **6231** of the rotation spur gear **623**, rotation of the input spur gear **619** in a counter-clockwise direction causes rotation of the rotation spur gear **623** in a clockwise direction. Still further, due to the engagement of the outer circumferential gear teeth **6171** of the fire spur gear **617** with the outer circumferential gear teeth **6081** of the firing spur gear **608**, rotation of the fire spur gear **617** in a counter-clockwise direction causes rotation of the firing spur gear **608** in a clockwise direction.

Firing spur gear **608** is mounted at an end of the firing gear shaft **604**, that has the first firing miter gear **610** mounted at its opposite end, such that rotation of the firing spur gear **608** in a clockwise direction also causes rotation of the firing gear shaft **604** and the first firing miter gear **610** in a clockwise direction.

The miter gear teeth **6101** of the first firing miter gear **610** engage the miter gear teeth **6121** of the second firing miter gear **612**, such that rotation of the first firing miter gear **610** in a clockwise direction causes rotation of the second firing miter gear **612** in a clockwise direction (when viewed into the page) about an axis that is perpendicular to the longitudinal axis of the firing gear shaft **604**. Likewise, the miter gear teeth **6121** of the second firing miter gear **612** engage the miter gear teeth **6141** of the third firing miter gear **614**, such that rotation of the second firing miter gear **612** in a clockwise direction causes rotation of the third firing miter gear **614** in a counter-clockwise direction. The third firing miter gear **614** is mounted at the proximal end of the second firing gear shaft **618** such that rotation of the third firing miter gear **614** in a counter-clockwise direction causes rotation of the second firing gear shaft **618** in a counter-clockwise direction.

FIG. 6(d) is a side perspective view, partially in section, of another section of the distal portion of the surgical device **11**. In particular, FIG. 6(d) illustrates additional components of the surgical device **11** that function to move a cutting and/or stapling element, e.g., to drive a staple pushing element and/or cutting blade through a section of tissue, according to the embodiment illustrated in FIGS. 3(f) and 4(d). FIG. 6(d) illustrates some of these firing driver **98** components in bold.

As set forth above, the second firing gear shaft **618** extends distally through the rotating tube **677** to eventually form the firing shaft **529**. The rotation of the fire shaft **527** in a counter-clockwise direction causes rotation of the input bevel gear **505b** in a counter-clockwise direction. By virtue of the meshing engagement of the gear teeth of the input bevel gear **505b** with the gear teeth of the lower idler bevel gear **549b**, rotation of the input bevel gear **505b** in a counter-clockwise direction about the longitudinal axis of the firing shaft **529** causes rotation of the lower idler bevel gear **549a** in a clockwise direction (when viewed from above) about the longitudinal axis of the hinge pin **551**. Likewise, by virtue of the meshing engagement of the gear teeth of the lower idler bevel gear **549b** with the gear teeth of the fire input bevel gear **533**, rotation of the lower idler bevel gear **549b** in a clockwise direction about the longitudinal axis of the hinge pin **551** causes rotation of the fire input bevel gear **533** in a clockwise

direction. Since the distal end of the fire input bevel gear **533** is non-rotatably engaged relative to the proximal end of the firing shaft **557**, rotation of the fire input bevel gear **533** in a clockwise direction causes rotation of the firing shaft **557** in a clockwise direction.

To further illustrate the cutting/stapling operation of the surgical device **11**, reference is next made to FIG. 5(e). FIG. 5(e) is a cross-sectional view of the jaw portion of the surgical device **11**, according to an embodiment of the present invention, in a fully closed position. In FIG. 5(e), the surgical device **11** is illustrated absent a section of tissue between the clamping surfaces **106**, **108** of the first and the second jaws **50**, **80**.

As illustrated in FIG. 5(e), the surgical device **11** is disposed within the second jaw **80**, and the cutting and stapling element **104** includes the replaceable staple cartridge **2600** of FIG. 5(e) that is replaceably mountable within the second jaw **80**. The replaceable staple cartridge **2600**, which was shown in an exploded view in FIG. 4(e), is shown assembled and mounted within the second jaw **80** in FIG. 5(e).

As illustrated in FIG. 5(e), the wedge **2603** has disposed thereon a blade **51** having a cutting edge **51a**. Alternatively, the cutting and stapling elements may be separately disposed. In the example embodiment illustrated in FIG. 5(e), the blade **51** has a tail region **2654** with a contact face **2653**. The blade **51** is rotatably coupled to the wedge **2603** around pivot **51b** to allow the blade **51** to rotate between a first and a second position. FIG. 5(e) illustrates the wedge **2603** and the blade **51** in several positions, labeled as positions A to E, as the wedge **2603** and the blade **51** travel from the distal end **2604c** to the proximal end **2604d** of the staple tray **2604**.

In the position labeled A, the wedge **2603** and the blade **51** are positioned at the distal end **2604c** of the staple tray **2604**. In the position labeled A, the wedge **2603** and the blade **51** are housed within a housing **2615** and the blade **51** is rotated relative to the wedge **2603** so as to be in a retracted position, e.g., the cutting edge **51a** facing upwards and is not exposed. The contact face **2653** initially faces the proximal end **2604d** of the staple tray **2604**.

In operation, rotation of the wedge driver **2605** in a clockwise direction (caused by its engagement with the distal end of the firing shaft **557**, which is described above as also rotating in a clockwise direction) causes the wedge **2603** and the blade **51** to advance to the position labeled B. In the position labeled B, the wedge **2603** and the blade **51** are positioned proximally relative to the distal end **2604c** of the staple tray **2604**. Specifically, in the position labeled B, the wedge **2603** and the blade **51** are positioned such that the contact face **2653** of the blade **51** begins to contact an actuating lip **2615a** of the housing **2615**. As the contact face **2653** of the blade **51** begins to contact the actuating lip **2615a** of the housing **2615**, the blade **51** begins to rotate relative to the wedge **2603**.

Further rotation of the wedge driver **2605** via the distal end of the firing shaft **557** causes the wedge **2603** and the blade **51** to advance to the position labeled C. In the position labeled C, the wedge **2603** and the blade **51** are positioned still further proximally relative to the distal end **2604c** of the staple tray **2604**. Specifically, in the position labeled C, the wedge **2603** and the blade **51** are positioned such that the contact face **2653** of the blade **51** has fully contacted the actuating lip **2615a** of the housing **2615**. When the contact face **2653** of the blade **51** has fully contacted the actuating lip **2615a** of the housing **2615**, the blade **51** is fully rotated relative to the wedge **2603** such that the cutting edge **51a** of the blade **51** is in an extended position, e.g., the cutting edge **51a** faces the proximal end **2604d** of the staple tray **2604**.

35

Further rotation of the wedge driver **2605** via the distal end of the firing shaft **557** causes the wedge **2603** and the blade **51** to advance to the position labeled D. In the position labeled D, the wedge **2603** and the blade **51** are positioned approximately at the midpoint between the distal end **2604c** and the proximal end **2604d** of the staple tray **2604**. In the position labeled D, the blade **51** is maintained in the extended position having the cutting edge **51a** facing the proximal end **2604d** of the staple tray **2604** so as to cut a section of tissue (not shown) that is clamped between the first jaw **50** and the second jaw **80**.

Further rotation of the wedge driver **2605** via the distal end of the firing shaft **557** causes the wedge **2603** and the blade **51** to advance to the position labeled E. In the position labeled E, the wedge **2603** and the blade **51** are positioned at the proximal end **2604d** of the staple tray **2604**. In the position labeled E, the blade **51** is still maintained in the extended position with the cutting edge **51a** facing the proximal end **2604d** of the staple tray **2604**. Here, however, the blade **51** is enclosed within a housing **2616** so that the cutting edge **51a** is not exposed.

The staples **2606** housed within the staple tray **2604** may simultaneously be fired with the movement of the blade **51** from the proximal end **80b** to the distal end **80a** of the second jaw **80**. For instance, rotation of the wedge driver **2605** via the distal end of the firing shaft **557** causes the wedge **2603** to be moved through the central channel **2604e** of the staple tray **2604**. As the wedge **2603** is moved from the distal end **2604c** to the proximal end **2604d** of the staple tray **2604** through the central channel **2604e**, the pair of sloped edges **2603b** of the wedge **2603** slideably engage the respective top surfaces **2607a** of the staple pushers **2607** and successively push the staple pushing fingers **2607c** of the staple pushers **2607** into, and thus the staples **2606** out of, the slots **2604h** in the staple tray **2604**. When the surgical device **11** is in the closed position, the rows **2702** of the staple guides **2703** align with the slots **2604h** of the staple tray **2604** in the second jaw **80** so that the staples **2606** maintained in the slots **2604h** of the staple tray **2604** are pushed by the staple pushing fingers **2607c** of the staple pushers **2607** into, and closed by, corresponding staple guides **2703** of the anvil member **2700**. The staple guides **2703** receive the prongs **2606b** of the staples **2606** when the surgical device **11** is fired and bend the prongs **2606b** so as to close the staples **2606**, thereby stapling the section of tissue.

It should be recognized that, according to various embodiments of the present invention, the blade **51** and the wedge **2603** may be moved in either a proximal or a distal direction in order to cut and/or staple a section of tissue disposed between the first jaw **50** and the second jaw **80**. Furthermore, it should be recognized that, according to various embodiments of the present invention, any mechanical arrangement that is configured to move the blade **51** and the wedge **2603** in order to cut and/or staple a section of tissue disposed between the first jaw **50** and the second jaw **80** may be employed.

Once the section of tissue may be cut and/or stapled, the surgical device **11** may be employed to return the wedge **2603** and the blade **51** to their initial positions. This may be particularly desirable when the surgical device **11** employs replaceable staple cartridges, e.g., replaceable staple cartridge **600** as illustrated in FIG. **4(e)**, thereby permitting the surgical device **11** to be used numerous times with different staple cartridges. Once the wedge **2603** and the blade **51** have been moved to their initial positions, the surgical device **11** may be used for a second or more time. To do so, the user may remove the spent staple cartridge **600** and insert in the surgical device **11a** new staple cartridge **600**, the distal end of the

36

firing shaft **557** being received within the proximally-facing opening **2605d** of the wedge driver **2605** of the new staple cartridge **600**. Of course, it should be recognized that this step of returning the wedge **2603** and the blade **51** to their initial positions may be performed either prior to, or subsequent to, removal of the surgical device **11** from the patient's body.

In order to return the wedge **2603** and the blade **51** to their initial positions, and as shown in FIG. **5(d)**, the function selector block **609** may remain in the fourth position, in which specific gears of the handle **1103** are engaged with each other. While the function selector block **609** is in the fourth position, the second rotatable drive shaft **1110b** may be caused to rotate, e.g., in a clockwise direction, such as by motor **100** (shown in FIG. **2(b)**). Rotation of the second rotatable drive shaft **1110b** in a clockwise direction causes rotation of the function shaft **611** in a clockwise direction. The input spur gear **619** and the firing spur gear **617** of the second rotatable drive shaft **1110b** are also caused to rotate in a clockwise direction. Due to the engagement of the outer circumferential gear teeth **6171** of the fire spur gear **617** with the outer circumferential gear teeth **6251** of the fire spur gear **625**, rotation of the fire spur gear **617** in a clockwise direction causes rotation of the fire spur gear **625** in a counter-clockwise direction. Likewise, due to the engagement of the outer circumferential gear teeth **6191** of the input spur gear **619** with the outer circumferential gear teeth **6231** of the rotation spur gear **623**, rotation of the input spur gear **619** in a clockwise direction causes rotation of the rotation spur gear **623** in a counter-clockwise direction. Still further, due to the engagement of the outer circumferential gear teeth **6171** of the fire spur gear **617** with the outer circumferential gear teeth **6081** of the firing spur gear **608**, rotation of the fire spur gear **617** in a clockwise direction causes rotation of the firing spur gear **608** in a counter-clockwise direction.

Firing spur gear **608** is mounted at an end of the firing gear shaft **604**, that has the first firing miter gear **610** mounted at its opposite end, such that rotation of the firing spur gear **608** in a counter-clockwise direction also causes rotation of each one of the firing gear shaft **604** and the first firing miter gear **610** in a counter-clockwise direction.

The miter gear teeth **6101** of the first firing miter gear **610** engage the miter gear teeth **6121** of the second firing miter gear **612**, such that rotation of the first firing miter gear **610** in a counter-clockwise direction causes rotation of the second firing miter gear **612** in a counter-clockwise direction (when viewed into the page) about an axis that is perpendicular to the longitudinal axis of the firing gear shaft **604**. Likewise, the miter gear teeth **6121** of the second firing miter gear **612** engage the miter gear teeth **6141** of the third firing miter gear **614**, such that rotation of the second firing miter gear **612** in a counter-clockwise direction causes rotation of the third firing miter gear **614** in a clockwise direction. The third firing miter gear **614** is mounted at the proximal end of the second firing gear shaft **618** such that rotation of the third firing miter gear **614** in a clockwise direction causes rotation of the second firing gear shaft **618** in a clockwise direction.

Referring to FIG. **6(d)**, the second firing gear shaft **618** extends distally through the rotating tube **677** to eventually form the firing shaft **529**. The rotation of the fire shaft **527** in a clockwise direction causes rotation of the input bevel gear **505b** in a clockwise direction. By virtue of the meshing engagement of the gear teeth of the input bevel gear **505b** with the gear teeth of the lower idler bevel gear **549b**, rotation of the input bevel gear **505b** in a clockwise direction about the longitudinal axis of the firing shaft **529** causes rotation of the lower idler bevel gear **549a** in a counter-clockwise direction

37

(when viewed from above) about the longitudinal axis of the hinge pin 551. Likewise, by virtue of the meshing engagement of the gear teeth of the lower idler bevel gear 549b with the gear teeth of the fire input bevel gear 533, rotation of the lower idler bevel gear 549b in a counter-clockwise direction about the longitudinal axis of the hinge pin 551 causes rotation of the fire input bevel gear 533 in a counter-clockwise direction. Since the distal end of the fire input bevel gear 533 is non-rotatably engaged relative to the proximal end of the firing shaft 557, rotation of the fire input bevel gear 533 in a counter-clockwise direction causes rotation of the firing shaft 557 in a counter-clockwise direction.

Referring to FIG. 5(e), the wedge driver 2605 is rotated in a counter-clockwise direction by the rotation of the firing shaft 557, such that wedge 2603 and the blade 51 travel from the proximal end 2604d to the distal end 2604c of the staple tray 2604 until, when the wedge 2603 and the blade 51 are positioned at the distal end 2604c of the staple tray 2604, e.g., the position that is labeled as position A, the wedge 2603 and the blade 51 are housed again within the housing 2615, the blade 51 being rotated relative to the wedge 2603 so as to be in a retracted position, e.g., the cutting edge 51a facing upwards and is not exposed.

Once the wedge 2603 and the blade 51 to their initial positions, the surgical device 11 may be employed to move the jaw portion 11a relative to the shaft portion 11b, e.g., to pivot the jaw portion 11a about axis B relative to the shaft portion 11b, back to its initial aligned position for the purposes of easing the removal of the surgical device from the incision of the patient. In order to perform this function, the surgical device 11 may be operated such that the function selector module 1110 is returned to the second functional position. As set forth above, in this second functional position, the function selector module 1110 causes engagement of the second rotatable drive shaft 1110b with an articulation driver 201.

Referring to FIG. 5(b), the first rotatable drive shaft 1110a is again caused to rotate, e.g., in a counter-clockwise direction, such as by motor 96 (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the first rotatable drive shaft 1110a and the proximal end of a selector shaft 601 are correspondingly sized and shaped, rotation of the first rotatable drive shaft 1110a in a counter-clockwise direction causes rotation of the selector shaft 601 in a counter-clockwise direction. By virtue of the threaded engagement of the threaded portion 607 of the selector shaft 601 within the threaded bore of the function selector block 609, rotation of the selector shaft 601 causes the function selector block 609 to move distally to, e.g., the second position, in which specific gears of the handle 1103 are engaged with each other.

Once the function selector block 609 is returned to the second position, the second rotatable drive shaft 1110b may be caused to rotate, e.g., in a clockwise direction, such as by motor 100 (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the second rotatable drive shaft 1110b and the proximal end of the function shaft 611 are correspondingly sized and shaped, rotation of the second rotatable drive shaft 1110b in a clockwise direction causes rotation of the function shaft 611 in a clockwise direction. The fire spur gear 617 of the second rotatable drive shaft 1110b is also caused to rotate in a clockwise direction. Due to the engagement of the outer circumferential gear teeth 6191 of the input spur gear 619 with the outer circumferential gear teeth 6231 of the articulation spur gear 623, rotation of the input spur gear 619 in a clockwise direction causes rotation of the articulation spur gear 623 in a counter-clockwise direction.

38

When the function selector block 609 is in the second position, the rotation spur gear 623 and the articulation spur gear 629 are engaged with the gear shaft 621 such that rotation of the rotation spur gear 623 in a counter-clockwise direction causes rotation of the gear shaft 621 in a counter-clockwise direction and also rotation of the articulation spur gear 629 in a counter-clockwise direction. By virtue of the meshing engagement of the outer circumferential gear teeth 6291 of the articulation spur gear 629 with the outer circumferential gear teeth 6871 of the articulation spur gear 687, rotation of the articulation spur gear 629 in a counter-clockwise direction causes rotation of the articulation spur gear 687 in a clockwise direction.

Rotation of the articulation spur gear 687, which is mounted at an end of the articulation gear shaft 685, in a clockwise direction causes rotation of the articulation gear shaft 685 in a clockwise direction and of the articulation worm gear 689, which is also mounted thereon, in a clockwise direction. By virtue of the engagement of outer circumferential worm gear teeth 6891 of the articulation worm gear 689 with the outer circumferential gear teeth 6911 of the articulation gear 691, rotation of the articulation worm gear 689 in a clockwise direction causes rotation of the articulation gear 691 in a clockwise direction (when viewed into the page) about a pivot axis that is perpendicular to a longitudinal axis of the articulation gear shaft 685. Likewise, rotation of the articulation gear 691 in a clockwise direction causes rotation of the articulation miter gear 692, that is mounted thereon, in a clockwise direction. The miter gear teeth 6921 of the articulation miter gear 692 engage the miter gear teeth 6961 of the articulation miter gear 696, such that rotation of the articulation miter gear 692 in a clockwise direction causes rotation of the articulation miter gear 696 in a clockwise direction.

The articulation miter gear 696 is mounted on the second articulation gear shaft 693. By virtue of the threaded engagement between the threaded rod portion 695 of the second articulation gear shaft 693 and the interior threaded bore of the articulation miter gear 696, rotation of the articulation miter gear 696 in a clockwise direction causes the second articulation gear shaft 693 to move, e.g., proximally (depending on the direction of threads on the second articulation gear shaft 693).

Referring to FIG. 6(b) proximal movement of second articulation gear shaft 693 and the articulation shaft 525 which it eventually forms, causes the rack 517 to also move proximally. By virtue of the engagement of the teeth of the rack 517 with the teeth of the rack gear 519, proximal movement of the rack 517 causes the rack gear 519, and the proximal articulation gear 515, to rotate in a counter-clockwise direction (when viewed from above). Also, by virtue of the engagement of the outer circumferential teeth of the proximal articulation gear 515 with the outer circumferential teeth of the distal articulation gear 547, rotation of the proximal articulation gear 515 in a counter-clockwise direction causes rotation of the distal articulation gear 547 in a clockwise direction. Since the distal articulation gear 547 is rotationally fixed relative to the distal pivot housing 543, rotation of the distal articulation gear 547 in a clockwise direction causes the jaw portion 11a to move, e.g., articulate, in a clockwise direction (when viewed from above) relative to the shaft portion 11b about the hinge pin 551. This movement, e.g., articulation, of the jaw portion 11a relative to the shaft portion 11b may continue until the longitudinal axes of the jaw portion 11a and the shaft portion 11b are aligned, thereby easing the removal of the surgical device 11 from the patient's incision.

Once the longitudinal axes of the jaw portion 11a and the shaft portion 11b have been aligned, the surgical device 11

may be employed to return the shaft portion **11b** to its initial position relative to the handle **1103**, e.g., by rotating the shaft portion **11b** relative to the handle **1103** about the longitudinal axis D of the handle **1103** until the shaft portion **11b** and the handle **1103** are in their initial, e.g., aligned, positions relative to each other. Again, this may be particularly desirable when the surgical device **11** employs replaceable staple cartridges, e.g., replaceable staple cartridge **600** as illustrated in FIG. 4(e), so as to return the surgical device **11** into a condition which permits it to be used numerous times with different staple cartridges. Once the shaft portion **11b** has been rotated back to its initial position relative to the handle **1103**, the surgical device **11** may be used for a second or more time. Of course, it should be recognized that this particular step may be performed either prior to, or subsequent to, removal of the surgical device **11** from the patient's body.

In order to rotate the shaft portion **11b** relative to the handle **1103** about the longitudinal axis D of the handle **1103** until the shaft portion **11b** and the handle **1103** are in their initial positions relative to each other, and as shown in FIG. 5(d), the surgical device **11** may be operated such that the function selector module **1110** is returned to the first functional position. As set forth above, in this first functional position, the function selector module **1110** causes engagement of the second rotatable drive shaft **1110b** with the rotation driver **202**.

Referring now to FIG. 5(a), the first rotatable drive shaft **1110a** is caused to rotate, e.g., such as by motor **96** (shown in FIG. 2(b)) in, e.g., a clockwise direction. Since the longitudinally-arranged bore of the first rotatable drive shaft **1110a** and the proximal end of a selector shaft **601** are correspondingly sized and shaped, rotation of the first rotatable drive shaft **1110a** in a clockwise direction causes rotation of the selector shaft **601** in a clockwise direction. By virtue of the threaded engagement of the threaded portion **607** of the selector shaft **601** within the threaded bore of the function selector block **609**, rotation of the selector shaft **601** in a clockwise direction causes the function selector block **609** to be returned to the distal-most, e.g., first position, in which specific gears of the handle **1103** are engaged with each other.

Once the function selector block **609** is returned to the first position, the second rotatable drive shaft **1110b** may be caused to rotate, e.g., in a clockwise direction, such as by motor **100** (shown in FIG. 2(b)). Since the longitudinally-arranged bore of the second rotatable drive shaft **1110b** and the proximal end of the function shaft **611** are correspondingly sized and shaped, rotation of the second rotatable drive shaft **1110b** in a clockwise direction causes rotation of the function shaft **611** in a clockwise direction. The input spur gear **619** of the second rotatable drive shaft **1110b** also rotates in a clockwise direction. Due to the engagement of the outer circumferential gear teeth **6191** of the input spur gear **619** with the outer circumferential gear teeth **6231** of the rotation spur gear **623**, rotation of the input spur gear **619** in a clockwise direction causes rotation of the rotation spur gear **623** in a counter-clockwise direction.

When the function selector block **609** is in the first position, the rotation spur gear **623** and the rotation spur gear **631** are engaged with the gear shaft **621** such that rotation of the rotation spur gear **623** in a counter-clockwise direction causes rotation of the gear shaft **621** in a counter-clockwise direction and also rotation of the rotation spur gear **631** in a counter-clockwise direction. By virtue of the meshing engagement of the outer circumferential gear teeth **6311** of the rotation spur gear **631** with the outer circumferential gear teeth **6391** of the rotation spur gear **639**, rotation of the rotation spur gear **631**

in a counter-clockwise direction causes rotation of the rotation spur gear **639** in a clockwise direction.

Rotation of the rotation spur gear **639**, which is mounted at an end of the rotation gear shaft **633**, in a clockwise direction causes rotation of the rotation gear shaft **633** in a clockwise direction and rotation of the rotation worm gear **641**, which is also mounted thereon, in a clockwise direction. By virtue of the engagement of outer circumferential worm gear teeth **6411** of the rotation worm gear **641** with the outer circumferential gear teeth **6431** of the rotation gear **643**, rotation of the rotation worm gear **641** in a clockwise direction causes rotation of the rotation gear **643** in a counter-clockwise direction (as viewed when looking into the page) about a pivot axis that is perpendicular to a longitudinal axis of the rotation gear shaft **633**. Likewise, rotation of the rotation gear **643** in a counter-clockwise direction causes rotation of the rotation miter gear **644**, that is mounted thereon, in a counter-clockwise direction. The miter gear teeth **6441** of the rotation miter gear **644** engage the miter gear teeth **6691** of the rotation miter gear **669**, such that rotation of the rotation miter gear **644** in a counter-clockwise direction causes rotation of the rotation miter gear **669** in a clockwise direction.

The rotation miter gear **669** is mounted on the second rotation gear shaft **665**, such that rotation of the rotation miter gear **669** in a clockwise direction causes rotation of the second rotation gear shaft **665** in a clockwise direction and of the rotation spur gear **673** in a clockwise direction. By virtue of the meshing engagement of the outer circumferential gear teeth **6731** of the rotation spur gear **673** with the outer circumferential gear teeth **6791** of the rotating tube spur gear **679**, rotation of the rotation spur gear **673** in a clockwise direction causes rotation of the rotating tube spur gear **679** in a counter-clockwise direction and also rotation of the rotating tube **677** mounted thereto in a counter-clockwise direction. The rotation of the rotating tube **677** in a counter-clockwise direction within the mouth **675** at the distal-most end of the handle **1103** may continue until the shaft portion **11b** and the handle **1103** are in their initial positions relative to each other.

As set forth above, according to an example embodiment of the present invention, the surgical device **11** may be configured as an attachment to, or may be integral with, a purely mechanical device driver system, such as that illustrated in FIG. 1. Alternatively, in another example embodiment of the present invention, the surgical device **11** may be an electro-mechanical device that is configured to stand alone, e.g., that includes various motors, drive shafts, control systems, etc., in an integral arrangement such that attachment to a separate electro-mechanical surgical system is eliminated. Such an arrangement is illustrated schematically in FIG. 2(c), and may include the advantage that the surgical device **11** is not connected prior to use to a separately-disposed drive system. In this embodiment, first motor **961** and second motor **1001** are arranged within the handle **1103**, such that the first and second rotatable drive shafts **1110a** and **1110b** are connected to, and driven by, the first and second motors **961**, **1001**, respectively. Still further, the surgical device **11** may be an electro-mechanical device that does not stand alone, but rather includes integrally one or more of motors, drive shafts, control systems, etc., while still being coupleable to a separate electro-mechanical surgical system that includes other ones of motors, drive shafts, control systems, etc.

In still another embodiment, the surgical device **11** may be configured as an attachment to, or may be integral with, an electro-mechanical surgical system, such as an electro-mechanical driver system **1610** illustrated in FIG. 2(a). FIGS. 3(a) through 6(d) illustrate an example embodiment of the surgical device **11** having such an arrangement, e.g., an

41

arrangement in which the surgical device **11** is coupleable via a flexible shaft (having various rotatable drive shafts included therein) to a separate drive unit (having an arrangement of motors for rotating the rotatable drive shafts) included therein. For example, FIG. 2(b) illustrates that the surgical device **11** may include a connection element **1104** that includes a quick connect sleeve **713** having quick connect slots **713a** that engage complementary quick connect elements **1664** of a flexible drive shaft **1620**, which is described in further detail below (see, for example, FIG. 10).

FIG. 2(a) is, according to an example embodiment of the present invention, a perspective view of an electro-mechanical driver component **1610** to which the surgical device **11** shown and described in connection with FIGS. 3(a) through 6(d) may be connected. Such an electro-mechanical surgical system is described in, e.g., U.S. patent application Ser. No. 09/723,715, filed on Nov. 28, 2000, now Issued as U.S. Pat. No. 6,793,652 on Sep. 21, 2004, U.S. patent application Ser. No. 09/836,781, filed on Apr. 17, 2001, now Issued as U.S. Pat. No. 6,981,941 on Jan. 3, 2006, U.S. patent application Ser. No. 09/887,789, filed on Jun. 22, 2001, now Issued as U.S. Pat. No. 7,032,798 on Apr. 25, 2006, and U.S. patent application Ser. No. 10/099,634, filed on Mar. 15, 2002, now Issued as U.S. Pat. No. 7,951,071 on May 31, 2011, each of which is expressly incorporated herein in their entirety by reference thereto. The electro-mechanical driver component **1610** may include, for example, a remote power console **1612**, which includes a housing **1614** having a front panel **1615**. Mounted on the front panel **1615** are a display device **1616** and indicators **1618a**, **1618b**. A flexible shaft **1620** may extend from the housing **1614** and may be detachably attached thereto via a first coupling **1622**. The distal end **1624** of flexible shaft **1620** may include a second coupling **1626** adapted to detachably couple, e.g., the surgical device **11** described above, to the distal end **1624** of the flexible shaft **1620**. The second coupling **1626** may also be adapted to detachably attach a different surgical instrument or attachment. In another example embodiment, the distal end **1624** of the flexible shaft **1620** may permanently attached to or be integral with a surgical instrument.

Any suitable arrangement of couplings and shafts, e.g., flexible or otherwise, may be employed in order to connect the surgical device **11** to the electro-mechanical drive component **1610** may be employed. For instance, FIGS. 7 through 10 illustrate an arrangement by which the surgical device **11** may be attached to the electro-mechanical power console **1610**. Referring to FIG. 7, there is seen a side view, partially in section, of the flexible shaft **1620**. According to an example embodiment, the flexible shaft **1620** includes a tubular sheath **1628**, which may include a coating or other sealing arrangement configured to provide a fluid-tight seal between the interior channel **1640** thereof and the environment. The sheath **1628** may be formed of a tissue-compatible, sterilizable elastomeric material. The sheath **1628** may also be formed of a material that is autoclavable. Disposed within the interior channel **1640** of the flexible shaft **1620**, and extending along the entire length thereof, may be a first rotatable drive shaft **94**, a second rotatable drive shaft **102**, a first steering cable **1634**, a second steering cable **1635**, a third steering cable **1636**, a fourth steering cable **1637** (it should be noted that such steering cables **1634**, **1635**, **1636** and **1637** may, in various embodiments of the present invention, be eliminated as the surgical device **11** may be considered to provide sufficient maneuverability without the steering capabilities of these particular steering cables) and a data transfer cable **1638**. FIG. 8 is a cross-sectional view of the flexible shaft **1620** taken along the line 8-8 illustrated in FIG. 7 and

42

further illustrates the several cables **94**, **102**, **1634**, **1635**, **1636**, **1637** and **1638**. Each distal end of the steering cables **1634**, **1635**, **1636**, **1637** is affixed to the distal end **1624** of the flexible shaft **1620**. Each of the several cables **94**, **102**, **1634**, **1635**, **1636**, **1637**, **1638** may be contained within a respective sheath.

The first rotatable drive shaft **94** and the second rotatable drive shaft **102** may be configured, for example, as highly flexible drive shafts, such as, for example, braided or helical drive cables. It should be understood that such highly flexible drive cables may have limited torque transmission characteristics and capabilities. It should also be understood that the surgical device **11**, or other attachments connected to the flexible shaft **1620**, may require a higher torque input than the torque transmittable by the drive shafts **94**, **102**. The drive shafts **94**, **102** may thus be configured to transmit low torque but high speed, the high-speed/low-torque being converted to low-speed/high-torque by gearing arrangements disposed, for example, at the distal end and/or the proximal end of the drive flexible shaft **1620**, in the surgical instrument or attachment and/or in the remote power console **1612**. It should be appreciated that such gearing arrangement(s) may be provided at any suitable location along the power train between the motors disposed in the housing **1614** and the attached surgical instrument or other attachment connected to the flexible shaft **1620**. Such gearing arrangement(s) may include, for example, a spur gear arrangement, a planetary gear arrangement, a harmonic gear arrangement, cycloidal drive arrangement, an epicyclic gear arrangement, etc. The surgical device **11** illustrated in FIGS. 3(a) through 6(d) hereinabove provide various gearing arrangements that provide the above-described conversions re: speed and/or torque transmission.

Referring now to FIG. 9, there is seen a rear end view of first coupling **1622**. The first coupling **1622** includes a first connector **1644**, a second connector **1648**, a third connector **1652** and a fourth connector **1656**, each rotatably secured to the first coupling **1622**. Each of the connectors **1644**, **1648**, **1652**, **1656** includes a respective recess **1646**, **1650**, **1654**, **1658**. As illustrated in FIG. 9, each recess **1646**, **1650**, **1654**, **1658** may be hexagonally shaped. It should be appreciated, however, that the recesses **1646**, **1650**, **1654**, **1658** may have any shape and configuration adapted to non-rotatably couple and rigidly attach the connectors **1644**, **1648**, **1652**, **1656** to respective drive shafts of the motor arrangement contained within the housing **1614**. It should be appreciated that complementary projections may be provided on respective drive shafts of the motor arrangement to thereby drive the drive elements of the flexible shaft **1620**. It should also be appreciated that the recesses may be provided on the drive shafts and complementary projections may be provided on the connectors **1644**, **1648**, **1652**, **1656**. Any other coupling arrangement configured to non-rotatably and releasably couple the connectors **1644**, **1648**, **1652**, **1656** and the drive shafts of the motor arrangement may be provided.

One of the connectors **1644**, **1648**, **1652**, **1656** is non-rotatably secured to the first drive shaft **94**, and another one of the connectors **1644**, **1648**, **1652**, **1656** is non-rotatably secured to the second drive shaft **102**. The remaining two of the connectors **1644**, **1648**, **1652**, **1656** engage with transmission elements configured to apply tensile forces on the steering cables **1634**, **1635**, **1636**, **1637** to thereby steer the distal end **1624** of the flexible shaft **1620**. The data transfer cable **1638** is electrically and logically connected with data connector **1660**. The data connector **1660** includes, for example, electrical contacts **1662**, corresponding to and equal in number to the number of individual wires contained in the data cable **1638**. The first coupling **1622** includes a key structure

43

1642 configured to properly orient the first coupling 1622 to a mating and complementary coupling arrangement disposed on the housing 1612. The key structure 1642 may be provided on either one, or both, of the first coupling 1622 and the mating and complementary coupling arrangement disposed on the housing 1612. The first coupling 1622 may include a quick-connect type connector, which may engage the first coupling 1622 to the housing 1612 by a simple pushing motion. Seals may be provided in conjunction with any of the several connectors 1644, 1648, 1652, 1656, 1660 to provide a fluid-tight seal between the interior of first coupling 1622 and the environment.

Referring now to FIG. 10, there is seen a front end view of the second coupling 1626 of the flexible shaft 1620. In the example embodiment, the second coupling 1626 includes a first connector 1666 and a second connector 1668, each rotatably secured to the second coupling 1626 and each non-rotatably secured to a distal end of a respective one of the first and second drive shafts 94, 102. A quick-connect type fitting 1664 is provided on the second coupling 1626 to detachably secure the device 11 thereto. The quick-connect type fitting 1664 may be, for example, a rotary quick-connect type fitting, a bayonet type fitting, etc. and may be a fitting complementary to the quick connect sleeve 713 illustrated in FIG. 2(b). A key structure 1674 may be provided on the second coupling 1626 and may be configured to properly align the surgical device 11 to the second coupling 1626. The key structure or other arrangement configured to properly align the surgical device 11 to the flexible shaft 1620 may be provided on either one, or both, of the second coupling 1626 and the surgical device 11. In addition, the key structure may be provided on the device 11, as illustrated in FIG. 2(b) as the slots 713a of the quick connect sleeve 713. A data connector 1670 having electrical contacts 1672 is also provided in the second coupling 1626. Like the data connector 1660 of first coupling 1622, the data connector 1670 of the second coupling 1626 includes contacts 1672 electrically and logically connected to the respective wires of the data transfer cable 1638 and the contacts 1662 of the data connector 1660. Seals may be provided in conjunction with the connectors 1666, 1668, 1670 to provide a fluid-tight seal between the interior of the second coupling 1626 and the environment.

Disposed within the housing 1614 of the remote power console 1612 are electro-mechanical driver elements configured to drive the drive shafts 94, 102 and the steering cables 1634, 1635, 1636, 1637 to thereby operate the electro-mechanical driver component 1610 and the surgical device 11 attached to the second coupling 1626. In the example embodiment illustrated schematically in FIG. 11, five electric motors 96, 100, 1684, 1690, 1696, each operated via a power source, may be disposed in the remote power console 1612. It should be appreciated, however, that any appropriate number of motors may be provided, and the motors may operate via battery power, line current, a DC power supply, an electronically controlled DC power supply, etc. It should also be appreciated that the motors may be connected to a DC power supply, which is in turn connected to line current and which supplies the operating current to the motors.

FIG. 11 illustrates schematically one possible arrangement of motors. An output shaft 1678 of a first motor 96 engages with the first connector 1644 of the first coupling 1622 when the first coupling 1622, and, therefore, the flexible shaft 1620, is engaged with the housing 1614 to thereby drive the first drive shaft 94 and the first connector 1666 of the second coupling 1626. Similarly, an output shaft 1682 of a second motor 100 engages the second connector 1648 of the first coupling 1622 when the first coupling 1622, and, therefore,

44

flexible shaft 1620 is engaged with the housing 1614 to thereby drive the second drive shaft 102 and the second connector 1668 of the second coupling 1626. An output shaft 1686 of a third motor 1684 engages the third connector 1652 of the first coupling 1622 when the first coupling 1622, and, therefore, the flexible shaft 1620, is engaged with the housing 1614 to thereby drive the first and second steering cables 1634, 1635 via a first pulley arrangement 1688. An output shaft 1692 of a fourth motor 1690 engages the fourth connector 1656 of the first coupling 1622 when the first coupling 1622, and, therefore, the flexible shaft 1620, is engaged with the housing 1614 to thereby drive the third and fourth steering cables 1636, 1637 via a second pulley arrangement 1694. The third and fourth motors 1684, 1690 may be secured on a carriage 1100, which is selectively movable via an output shaft 1698 of a fifth motor 1696 between a first position and a second position to selectively engage and disengage the third and fourth motors 1684, 1690 with the respective pulley arrangement 1688, 1694 to thereby permit the flexible shaft 1620 to become taut and steerable or limp as necessary. It should be appreciated that other mechanical, electrical and/or electro-mechanical mechanisms, etc., may be used to selectively engage and disengage the steering mechanism. The motors may be arranged and configured as described, for example, in U.S. patent application Ser. No. 09/510,923, filed on Feb. 22, 2000, entitled "A Carriage Assembly for Controlling a Steering Wire Mechanism Within a Flexible Shaft," now U.S. Pat. No. 6,517,565, Issued on Feb. 11, 2003, which is expressly incorporated herein in its entirety by reference thereto. It should also be appreciated that, in accordance with other embodiments of the present invention, the steering mechanism may not be present at all, the surgical device 11 providing articulation between the jaw portion 11a and the shaft portion 11b so as to maneuver the surgical device 11 within a surgical site.

It should be appreciated that any one or more of the motors 96, 100, 1684, 1690, 1696 may be, for example, a high-speed/low-torque motor, a low-speed/high-torque motor, etc. As indicated above, the first rotatable drive shaft 94 and the second rotatable drive shaft 102 may be configured to transmit high speed and low torque. Thus, the first motor 96 and the second motor 100 may be configured as high-speed/low-torque motors. Alternatively, the first motor 96 and the second motor 100 may be configured as low-speed/high-torque motors with a torque-reducing/speed-increasing gear arrangement disposed between the first motor 96 and the second motor 100 and a respective one of the first rotatable drive shaft 94 and the second rotatable drive shaft 102. Such torque-reducing/speed-increasing gear arrangements may include, for example, a spur gear arrangement, a planetary gear arrangement, a harmonic gear arrangement, cycloidal drive arrangement, an epicyclic gear arrangement, etc. It should be appreciated that any such gear arrangement may be disposed within the remote power console 1612 or in the proximal end of the flexible shaft 1620, such as, for example, in the first coupling 1622. It should be appreciated that the gear arrangement(s) may be provided at the distal and/or proximal ends of the first rotatable drive shaft 94 and/or the second rotatable drive shaft 102 to prevent windup and breakage thereof. As set forth above, the example embodiment described hereinabove includes various such gearing arrangements for providing appropriate speed/torque function.

Referring now to FIG. 12, there is seen a schematic view of the electro-mechanical driver component 1610. A controller 1122 is provided in the housing 1614 of remote power console 1612 and is configured to control all functions and operations of the electro-mechanical driver component 1610 and

the linear clamping, cutting and stapling device **11** or other surgical instrument or attachment attached to the flexible shaft **1620**. A memory unit **1130** is provided and may include memory devices, such as, a ROM component **1132**, a RAM component **1134**, etc. The ROM component **1132** is in electrical and logical communication with the controller **1122** via a line **1136**, and the RAM component **1134** is in electrical and logical communication with controller **1122** via line **1138**. The RAM component **1134** may include any type of random-access memory, such as, for example, a magnetic memory device, an optical memory device, a magneto-optical memory device, an electronic memory device, etc. Similarly, the ROM component **1132** may include any type of read-only memory, such as, for example, a removable memory device, such as a PC-Card or PCMCIA-type device. It should be appreciated that the ROM component **1132** and the RAM component **1134** may be configured as a single unit or may be separate units and that the ROM component **1132** and/or the RAM component **1134** may be provided in the form of a PC-Card or PCMCIA-type device.

The controller **1122** is further connected to the front panel **1615** of the housing **1614** and, more particularly, to the display device **1616** via a line **1154** and the indicators **1618a**, **1618b** via respective lines **1156**, **1158**. The lines **1116**, **1118**, **1124**, **1126**, **1128** electrically and logically connect controller **1122** to first, second, third, fourth and fifth motors **96**, **100**, **1684**, **1690**, **1696**, respectively. A wired remote control unit ("RCU") **1150** is electrically and logically connected to the controller **1122** via a line **1152**. A wireless RCU **1148** is also provided and communicates via a wireless link **1160** with a receiving/sending unit **1146** connected via a line **1144** to a transceiver **1140**. The transceiver **1140** is electrically and logically connected to the controller **1122** via a line **1142**. The wireless link **1160** may be, for example, an optical link, such as an infrared link, a radio link or any other form of wireless communication link.

A switch device **1186**, which may include, for example, an array of DIP switches, may be connected to the controller **1122** via a line **1188**. The switch device **1186** may be configured, for example, to select one of a plurality of languages used in displaying messages and prompts on the display device **1616**. The messages and prompts may relate to, for example, the operation and/or the status of the electro-mechanical driver component **1610** and/or to the surgical device **11** attached thereto.

According to the example embodiment of the present invention, a first encoder **1106** is provided within the second coupling **1626** and is configured to output a signal in response to and in accordance with the rotation of the first drive shaft **94**. A second encoder **1108** is also provided within the second coupling **626** and is configured to output a signal in response to and in accordance with the rotation of the second drive shaft **102**. The signal output by each of the encoders **1106**, **1108** may represent the rotational position of the respective drive shaft **94**, **102** as well as the rotational direction thereof. These encoders may be an arrangement of light sources, e.g., LEDs, and optical fibers as illustrated for instance in FIG. 6(e). Alternatively, such encoders **1106**, **1108** may include, for example, Hall-effect devices, optical devices, etc. Although the encoders **1106**, **1108** are described as being disposed within the second coupling **1626**, it should be appreciated that the encoders **1106**, **1108** may be provided at any location between the motor system and the surgical device **11**. It should be appreciated that providing the encoders **1106**, **1108** within the second coupling **1626** or at the distal end of the flexible shaft **1620** may provide an accurate determination of the drive shaft rotation. If the encoders **1106**, **1108** are

disposed at the proximal end of the flexible shaft **1620**, windup of the first and second rotatable drive shafts **94**, **102** may result in measurement error.

FIG. 13 is a schematic view of an encoder **1106**, **1108**, which includes a Hall-effect device. Mounted non-rotatably on the drive shaft **94**, **102** is a magnet **1240** having a north pole **1242** and a south pole **1244**. The encoder **1106**, **1108** further includes a first sensor **1246** and second sensor **1248**, which are disposed approximately 90° apart relative to the longitudinal, or rotational, axis of the drive shaft **94**, **102**. The output of the sensors **1246**, **1248** is persistent and changes its state as a function of a change of polarity of the magnetic field in the detection range of the sensor. Thus, based on the output signal from the encoders **1106**, **1108**, the angular position of the drive shaft **94**, **102** may be determined within one-quarter revolution and the direction of rotation of the drive shaft **94**, **102** may be determined. The output of each encoder **1106**, **1108** is transmitted via a respective line **1110**, **1112** of data transfer cable **1638** to controller **1122**. The controller **1122**, by tracking the angular position and rotational direction of the drive shafts **94**, **102** based on the output signal from the encoders **1106**, **1108**, may thereby determine the position and/or state of the components of the surgical device connected to the electro-mechanical driver component **1610**. That is, by counting the revolutions of the drive shaft **94**, **102**, the controller **1122** may determine the position and/or state of the components of the surgical device connected to the electro-mechanical driver component **1610**.

For example, the advancement distance of the first jaw **50** relative to the second jaw **80** and of the wedge **2603** may be functions of, and ascertainable on the basis of, the rotation of the respective drive shafts **94**, **102**. By ascertaining an absolute position of the first jaw **50** and the wedge **2603** at a point in time, the relative displacement of the first jaw **50** and the wedge **2603**, based on the output signal from the encoders **1106**, **1108** and the known pitches of the clamp screw **559** and of the wedge driver **2605**, may be used to ascertain the absolute position of the first jaw **50** and the wedge **2603** at all times thereafter. The absolute position of the first jaw **50** and the wedge **2603** may be fixed and ascertained at the time that the surgical device **11** is first coupled to the flexible shaft **1620**. Alternatively, the position of the first jaw **50** and the wedge **603** relative to, for example, the second jaw **80** may be determined based on the output signal from the encoders **1106**, **1108**.

Still further, the surgical device **11** may include optical sensors **3001**, **3002**, **3003** and **3004**, as shown, for example, in FIG. 3(b). These optical sensors **3001**, **3002**, **3003** and **3004** may operate in conjunction with the function selector block **609**. Depending on the position of the function selector block **609**, corresponding signals to and from various ones of the optical sensors **3001**, **3002**, **3003** and **3004** are blocked, thereby providing a suitable controller with an indication when the surgical device **11** is in one of the four above-described functional positions, e.g., rotation, articulation, opening/closing of the jaws relative to each other, and firing the cutting and/or stapling mechanism.

As discussed above in connection with FIGS. 2(b) and 10, the surgical device **11** may include a data connector **1272** adapted by size and configuration to electrically and logically connect to connector **1670** of second coupling **1626**. In the example embodiment, the data connector **1272** includes contacts **1276** equal in number to the number of contacts **1672** of connector **1670**. The memory module **6041** is electrically and logically connected with the data connector **1272**. Memory module **6041** may be in the form of, for example, an EEPROM, EPROM, etc. and may be contained, for example,

47

within the staple tray 2604 of the replaceable staple cartridge 2600 in the second jaw 80 of the surgical device 11, as illustrated in FIG. 3(f).

FIG. 14 schematically illustrates the memory module 6041. As seen in FIG. 14, data connector 1272 includes contacts 1276, each electrically and logically connected to the memory module 6041 via a respective line, e.g., flexible data cable 1278. The memory module 6041 may be configured to store, for example, a serial number data 1180, an attachment type identifier (ID) data 1182 and a usage data 1184. The memory module 6041 may additionally store other data. Both the serial number data 1180 and the ID data 1182 may be configured as read-only data. The serial number data 1180 and/or the ID data 1182 may be stored in a read-only section of the memory module 6041. In the example embodiment, serial number data 1180 may be data uniquely identifying the particular surgical device, whereas the ID data 1182 may be data identifying the type of the attachment, such as, e.g., for an electro-mechanical driver component 1610 to which other types of surgical instruments or attachments are attachable. The usage data 1184 represents usage of the particular attachment, such as, for example, the number of times the first jaw 50 of the surgical device 11 has been opened and closed, or the number of times that the wedge 2603 of the surgical device 11 has been advanced. The usage data 1184 may be stored in a read/write section of the memory module 6041.

It should be appreciated that the attachment attachable to the distal end 1624 of the flexible shaft 1620, e.g., surgical device 11, may be designed and configured to be used a single time or multiple times. The attachment may also be designed and configured to be used a predetermined number of times. Accordingly, the usage data 1184 may be used to determine whether the surgical device 11 has been used and whether the number of uses has exceeded the maximum number of permitted uses. As more fully described below, an attempt to use the attachment after the maximum number of permitted uses has been reached will generate an ERROR condition.

Referring again to FIG. 12, the controller 1122 is configured to read the ID data 1182 from the memory module 6041 of the surgical device 11 when the surgical device 11 is initially connected to the flexible shaft 1620. The memory module 6041 is electrically and logically connected to the controller 1122 via the line 1120 of the data transfer cable 1638. Based on the read ID data 1182, the controller 1122 is configured to read or select from the memory unit 1130, an operating program or algorithm corresponding to the type of surgical instrument or attachment connected to the flexible shaft 1620. The memory unit 1130 is configured to store the operating programs or algorithms for each available type of surgical instrument or attachment, the controller 1122 selecting and/or reading the operating program or algorithm from the memory unit 1130 in accordance with the ID data 1182 read from the memory module 6041 of an attached surgical instrument or attachment. As indicated above, the memory unit 1130 may include a removable ROM component 1132 and/or RAM component 1134. Thus, the operating programs or algorithms stored in the memory unit 1130 may be updated, added, deleted, improved or otherwise revised as necessary. The operating programs or algorithms stored in the memory unit 1130 may be customizable based on, for example, specialized needs of the user. A data entry device, such as, for example, a keyboard, a mouse, a pointing device, a touch screen, etc., may be connected to the memory unit 1130 via, for example, a data connector port, to facilitate the customization of the operating programs or algorithms. Alternatively or additionally, the operating programs or algorithms may be customized and preprogrammed into the memory unit

48

1130 remotely from the electro-mechanical driver component 1610. It should be appreciated that the serial number data 1180 and/or usage data 1184 may also be used to determine which of a plurality of operating programs or algorithms is read or selected from the memory unit 1130. It should be appreciated that the operating program or algorithm may alternatively be stored in the memory module 6041 of the surgical device 11 and transferred to the controller 1122 via the data transfer cable 1638. Once the appropriate operating program or algorithm is read by or selected by or transmitted to, the controller 1122, the controller 1122 causes the operating program or algorithm to be executed in accordance with operations performed by the user via the wired RCU 1150 and/or the wireless RCU 1148. As indicated hereinabove, the controller 1122 is electrically and logically connected with the first, second, third, fourth and fifth motors 96, 100, 1684, 1690, 1696 via respective lines 1116, 1118, 1124, 1126, 1128 and is configured to control such motors 96, 100, 1684, 1690, 1696 in accordance with the read, selected or transmitted operating program or algorithm via the respective lines 1116, 1118, 1124, 1126, 1128.

Referring now to FIG. 15, there is seen a schematic view of wireless RCU 1148. Wireless RCU 1148 includes a steering controller 1300 having a plurality of switches 1302, 1304, 1306, 1308 arranged under a four-way rocker 1310. The operation of switches 1302, 1304, via rocker 1310, controls the operation of first and second steering cables 1634, 1635 via third motor 1684. Similarly, the operation of switches 1306, 1308, via rocker 1310, controls the operation of third and fourth steering cables 1636, 1637 via fourth motor 1692. It should be appreciated that rocker 1310 and switches 1302, 1304, 1306, 1308 are arranged so that the operation of switches 1302, 1304 steers the flexible shaft 1620 in the north-south direction and that the operation of switches 1306, 1308 steers the flexible shaft 1620 in the east-west direction. Reference herein to north, south, east and west is made to a relative coordinate system. Alternatively, a digital joystick, an analog joystick, etc. may be provided in place of rocker 1310 and switches 1302, 1304, 1306, 1308. Potentiometers or any other type of actuator may also be used in place of switches 1302, 1304, 1306, 1308.

The wireless RCU 1148 further includes a steering engage/disengage switch 1312, the operation of which controls the operation of fifth motor 696 to selectively engage and disengage the steering mechanism. The wireless RCU 1148 also includes a two-way rocker 1314 having first and second switches 1316, 1318 operable thereby. The operation of these switches 1316, 1318 controls certain functions of the electro-mechanical driver component 1610 and any surgical instrument or attachment, such as the surgical device 11, attached to the flexible shaft 1620 in accordance with the operating program or algorithm corresponding to the attached device. For example, operation of the two-way rocker 1314 may control the opening and closing of the first jaw 50 and the second jaw 80 of the surgical device 11. The wireless RCU 1148 is provided with yet another switch 1320, the operation of which may further control the operation of the electro-mechanical driver component 1610 and the device attached to the flexible shaft 1620 in accordance with the operating program or algorithm corresponding to the attached device. For example, operation of the switch 1320 may initiate the advancement of the wedge 603 of the surgical device 11.

The wireless RCU 1148 includes a controller 1322, which is electrically and logically connected with the switches 1302, 1304, 1306, 1308 via line 1324, with the switches 1316, 1318 via line 1326, with switch 1312 via line 1328 and with switch 1320 via line 1330. The wireless RCU 1148 may include

indicators **1618a'**, **1618b'**, corresponding to the indicators **1618a**, **1618b** of front panel **1615**, and a display device **1616'**, corresponding to the display device **1616** of the front panel **1615**. If provided, the indicators **1618a'**, **1618b'** are electrically and logically connected to controller **1322** via respective lines **1332**, **1334**, and the display device **1616'** is electrically and logically connected to controller **1322** via line **1336**. The controller **1322** is electrically and logically connected to a transceiver **1338** via line **1340**, and the transceiver **1338** is electrically and logically connected to a receiver/transmitter **1342** via line **1344**. A power supply, for example, a battery, may be provided in wireless RCU **1148** to power the same. Thus, the wireless RCU **1148** may be used to control the operation of the electro-mechanical driver component **1610** and the device **11** attached to the flexible shaft **1620** via wireless link **1160**.

The wireless RCU **1148** may include a switch **1346** connected to a controller **1322** via line **1348**. Operation of the switch **1346** transmits a data signal to the transmitter/receiver **1146** via wireless link **1160**. The data signal includes identification data uniquely identifying the wireless RCU **1148**. This identification data is used by the controller **1122** to prevent unauthorized operation of the electro-mechanical driver component **1610** and to prevent interference with the operation of the electro-mechanical driver component **610** by another wireless RCU. Each subsequent communication between the wireless RCU **1148** and the electro-mechanical device surgical **610** may include the identification data. Thus, the controller **1122** may discriminate between wireless RCUs and thereby allow only a single, identifiable wireless RCU **1148** to control the operation of the electro-mechanical driver component **1610** and the surgical device **11** attached to the flexible shaft **1620**.

Based on the positions of the components of the surgical device attached to the flexible shaft **1620**, as determined in accordance with the output signals from the encoders **1106**, **1108**, the controller **1122** may selectively enable or disable the functions of the electro-mechanical driver component **1610** as defined by the operating program or algorithm corresponding to the attached device. For example, for the surgical device **11**, the firing function controlled by the operation of the switch **1320** may be disabled unless the space or gap between the first jaw **50** and the second jaw **80** is determined to be within an acceptable range.

Referring now to FIG. **16**, there is seen a schematic view of a wired RCU **1150**. In the example embodiment, wired RCU **1150** includes substantially the same control elements as the wireless RCU **1148** and further description of such elements is omitted. Like elements are indicated in FIG. **16** with an accompanying prime. It should be appreciated that the functions of the electro-mechanical driver component **1610** and the device attached to the flexible shaft **1620**, e.g., the surgical device **11**, may be controlled by the wired RCU **1150** and/or by the wireless RCU **1148**. In the event of a battery failure, for example, in the wireless RCU **1148**, the wired RCU **1150** may be used to control the functions of the electro-mechanical driver component **1610** and the device attached to the flexible shaft **1620**.

As described hereinabove, the front panel **1615** of the housing **1614** includes the display device **1616** and the indicators **1618a**, **1618b**. The display device **1616** may include an alpha-numeric display device, such as an LCD display device. The display device **1616** may also include an audio output device, such as a speaker, a buzzer, etc. The display device **1616** is operated and controlled by controller **1122** in accordance with the operating program or algorithm corresponding to the device attached to the flexible shaft **1620**, e.g.,

the surgical device **11**. If no surgical instrument or attachment is so attached, a default operating program or algorithm may be read by or selected by or transmitted to controller **1122** to thereby control the operation of the display device **1616** as well as the other aspects and functions of the electro-mechanical driver component **1610**. If the surgical device **11** is attached to the flexible shaft **1620**, the display device **1616** may display, for example, data indicative of the gap between the first jaw **50** and the second jaw **80** as determined in accordance with the output signal of encoders **1106**, **1108**, as more fully described hereinabove.

Similarly, the indicators **1618a**, **1618b** are operated and controlled by the controller **1122** in accordance with the operating program or algorithm corresponding to the device attached to the flexible shaft **1620**, e.g., the surgical device **11**. The indicator **1618a** and/or the indicator **1618b** may include an audio output device, such as a speaker, a buzzer, etc., and/or a visual indicator device, such as an LED, a lamp, a light, etc. If the surgical device **11** is attached to the flexible shaft **1620**, the indicator **1618a** may indicate, for example, that the electro-mechanical driver component **1610** is in a power ON state, and the indicator **1618b** may, for example, indicate whether the gap between the first jaw **50** and the second jaw **80** is determined to be within the acceptable range. It should be appreciated that although two indicators **1618a**, **1618b** are described, any number of additional indicators may be provided as necessary. Additionally, it should be appreciated that although a single display device **1616** is described, any number of additional display devices may be provided as necessary.

The display device **1616'** and the indicators **1618a'**, **1618b'** of wired RCU **1150** and the display device **1616"** and indicators **1618a"**, **1618b"** of the wireless RCU **1148** are similarly operated and controlled by respective controller **1322**, **1322'** in accordance with the operating program or algorithm of the device attached to the flexible shaft **1620**.

FIGS. **15** and **16** illustrate schematic views of a wireless and a wired RCU, respectively, each of which is configured to control, upon actuation by an operator, the various functions to be performed by the surgical device **11**, e.g., rotation, articulation, opening/closing of the jaws relative to each other and firing a cutting and/or stapling mechanism. As set forth above, the surgical device **11** may also include various other arrangements for controlling the performance of these functions. For example, FIG. **3(b)** illustrates that, in accordance with an embodiment of the present invention, the surgical device **11** may include a rotation/articulation control device **3006** and/or an open/close/fire control device **3007**.

In the embodiment shown, the rotation/articulation control device **3006** is a joystick-type device that is positioned on a top surface of the handle **1103** so as to be actuatable by an operator's thumb when the operator is holding the handle **1103**. The rotation/articulation control device **3006** may function similarly to the above-described four-way rocker **1310** of the wireless RCU **1148**, in that movement of the rotation/articulation control device **3006** in a north-south direction may control the operation of the rotation driver **202** when the surgical device **11** is in a rotation mode, e.g., when the function selector block **609** is positioned in the first functional position. For example, when the rotation/articulation control device **3006** is moved by an operator in a north direction, e.g., by pushing the rotation/articulation control device **3006** distally, the rotation driver **202** may be actuated so as to cause the second rotatable drive shaft **1110b** to rotate in a direction suitable to cause the shaft portion **111b** to rotate in a clockwise direction relative to the handle **1103**. Likewise, when the rotation/articulation control device **3006** is moved

51

by an operator in a south direction, e.g., by pushing the rotation/articulation control device **3006** proximally, the rotation driver **202** may be actuated so as to cause the second rotatable drive shaft **1110b** to rotate in a direction suitable to cause the shaft portion **11b** to rotate in a counter-clockwise direction relative to the handle **1103**. The surgical device **11** may be configured such that, if the function selector block **609** is not positioned in the first functional position, e.g., in rotation mode, the rotation driver **202** may be locked-out, e.g., prevented from moving whereby movement of the rotation/articulation control device **3006** in either of the north or south directions will not cause actuation of the rotation driver **202**.

The rotation/articulation control device **3006** may also function similarly to the above-described four-way rocker **1310** of the wireless RCU **1148**, in that movement of the rotation/articulation control device **3006** in an east-west direction may control the operation of the articulation driver **201** when the surgical device **11** is in an articulation mode, e.g., when the function selector block **609** is positioned in the second functional position. For example, when the rotation/articulation control device **3006** is moved by an operator in a west direction, e.g., by pushing the rotation/articulation control device **3006** to the left, the articulation driver **201** may be actuated so as to cause the second rotatable drive shaft **1110b** to rotate in a direction suitable to cause the jaw portion **11a** to rotate in a clockwise direction relative to the shaft portion **11b**. Likewise, when the rotation/articulation control device **3006** is moved by an operator in an east direction, e.g., by pushing the rotation/articulation control device **3006** to the right, the articulation driver **201** may be actuated so as to cause the second rotatable drive shaft **1110b** to rotate in a direction suitable to cause the jaw portion **11a** to rotate in a counter-clockwise direction relative to the shaft portion **11b**. The surgical device **11** may be configured such that, if the function selector block **609** is not positioned in the second functional position, e.g., in articulation mode, the articulation driver **201** may be locked-out, e.g., prevented from moving whereby movement of the rotation/articulation control device **3006** in either of the east or west directions will not cause actuation of the articulation driver **201**.

Also, in the embodiment shown, the open/close/fire control device **3007** is a trigger-type device that is suitably positioned, e.g., on a bottom surface of the handle **1103**, and sized so as to be actuable by an operator's forefinger when the operator is holding the handle **1103**. The open/close/fire control device **3007** may function similarly to the above-described two-way rocker **1314** of the wireless RCU **1148**, in that movement of the open/close/fire control device **3007** in first and second directions may control the operation of the clamping driver **88** when the surgical device **11** is in a clamping mode, e.g., when the function selector block **609** is positioned in the third functional position. For example, when the open/close/fire control device **3007** is moved by an operator in a first direction, e.g., by depressing a top portion of the open/close/fire control device **3007**, the clamping driver **88** may be actuated so as to cause the second rotatable drive shaft **1110b** to rotate in a direction suitable to cause the first jaw to open relative to the second jaw **80**. Likewise, when the open/close/fire control device **3007** is moved by an operator in a second direction, e.g., by depressing a bottom portion of the open/close/fire control device **3007**, the clamping driver **88** may be actuated so as to cause the second rotatable drive shaft **1110b** to rotate in a direction suitable to cause the first jaw to close relative to the second jaw **80**. The surgical device **11** may be configured such that, if the function selector block **609** is not positioned in the third functional position, e.g., in clamping mode, the clamping driver **88** may be locked-out,

52

e.g., prevented from moving whereby movement of the open/close/fire control device **3007** in either of the first or second directions will not cause actuation of the clamping driver **88**.

The open/close/fire control device **3007** may also function similarly to the above-described switch **1320** of the wireless RCU **1148**, in that movement of the open/close/fire control device **3007** in a first and second direction may control the operation of the firing driver **98** when the surgical device **11** is in a firing mode, e.g., when the function selector block **609** is positioned in the fourth functional position. For example, when the open/close/fire control device **3007** is moved by an operator in a first direction, e.g., by depressing a top portion of the open/close/fire control device **3007**, the firing driver **98** may be actuated so as to cause the second rotatable drive shaft **1110b** to rotate in a direction suitable to cause the firing shaft **557** and the wedge driver **2605** to rotate in a clockwise direction to thereby drive the wedge **2603** and/or the blade **51** through a section of tissue. Likewise, when the open/close/fire control device **3007** is moved by an operator in a second direction, e.g., by depressing a bottom portion of the open/close/fire control device **3007**, the firing driver **98** may be actuated so as to cause the firing shaft **557** and the wedge driver **2605** to rotate in a counter-clockwise direction to thereby retract the wedge **2603** and/or the blade **51** back to their initial positions. The surgical device **11** may be configured such that, if the function selector block **609** is not positioned in the fourth functional position, e.g., in firing mode, the firing driver **98** may be locked-out, e.g., prevented from moving whereby movement of the open/close/fire control device **3007** in either of the first or second directions will not cause actuation of the firing driver **98**.

The transmission of signals from the rotation/articulation control device **3006** and/or the open/close/fire control device **3007** to appropriate controllers may be performed either by wired connection or wireless transmission, using the communication arrangements similar to those illustrated in FIGS. **15** and **16**, respectively.

The surgical device **11** of the present invention may also employ an imaging arrangement, e.g., a camera. In such an arrangement, an imaging device may be positioned at a suitable location of the surgical device **11** so as to provide to an operator imaging data corresponding to a surgical site. Advantageously, the imaging device is articulatable along with the jaw portion **11a**, such that appropriate image data may be provided to an operator irrespective of whether the jaw portion **11a** has been rotated clockwise or counter-clockwise relative to the shaft portion **11b**.

As set forth above, one problem with conventional surgical devices, and in particular with the conventional linear clamping, cutting and stapling devices such as that illustrated in FIG. **1**, is that the opposing jaws may be difficult to maneuver within a patient. It may be necessary for a surgeon to move the opposing jaws between various angles in order to position the desired tissue between the opposing jaws. However, it may also be desirable to make an incision in a patient that is as small as possible, and the small size of an incision limits the degree to which the opposing jaws may be maneuvered. Example embodiments of the present invention may provide improved maneuverability of a surgical device, e.g., the surgical device **11**, within a patient.

Another problem with the conventional surgical devices, and in particular with the foregoing linear clamping, cutting and stapling devices such as that illustrated in FIG. **1**, is that the opposing jaws may not be sufficiently hemostatic. Specifically, the opposing jaws of the foregoing surgical devices may not be clamped together with sufficient force, thereby reducing the effectiveness of the surgical device. Example

53

embodiments of the present invention may provide improved clamping of a section of tissue disposed between the jaws of a surgical device, e.g., the surgical device **11**, thereby providing a sufficiently hemostatic condition with respect to the clamped section of tissue.

As set forth above, the surgical device of the present invention may employ motors to drive the first and second rotatable drive shafts **1110a** and **1110b**, wherein the motors are integral with the surgical device **11**. For example, FIG. 2(c) is a schematic diagram that illustrates an arrangement of the surgical device **11**, according to an example embodiment of the present invention, in which the first motor **961** and second motor **1001** are arranged within the handle **1103**, such that the first and second rotatable drive shafts **1110a** and **1110b** are connected to the first and second motors **961**, **1001**, respectively. FIGS. 17(a) through 18(d) provide additional details of such an embodiment, and particularly, an arrangement in which various components, e.g., motors, power source, etc., are integral with the device.

FIG. 17(a) is a side perspective view of such a surgical device, according to an example embodiment of the present invention. Referring now to FIG. 17(a), there is shown a surgical device **800** that is configured to stand alone, e.g., that includes various motors, drive shafts, control systems, etc., in an integral arrangement such that attachment to a separate electro-mechanical surgical system is eliminated. Such an arrangement may include the advantage that the surgical device **800** is not connected prior to use to a separately-disposed drive system. The surgical device **800** is configured so as to be particularly well-suited for insertion into the body of a patient, e.g., via a cannula (not shown). In the embodiment shown, the surgical device **800** is a clamping, cutting and stapling device. The surgical device **800** includes a jaw portion **811a** that is pivotably coupled to a shaft portion **811b** by a hinge portion **811c**. The jaw portion **811a** includes a first jaw **850** having a distal end and a proximal end, and a second jaw **880** having a distal end and a proximal end. The first jaw **850** and the second jaw **880** are pivotably coupled relative to each other at or near their respective proximal ends. As shown, the first jaw **850** and the second jaw **880** are pivotable relative to each other about pivot axis A. In this arrangement, the jaws are configured such that, upon opening and closing of the first jaw **850** relative to the second jaw **880** and at points in the movement of the first jaw **850** relative to the second jaw **880**, both the first jaw **850** and the second jaw **880**, e.g., their longitudinal axes, remain within a plane. It should be understood, however, that the surgical device **800** may instead be configured such that the first jaw **850** and the second jaw **880** are pivotable relative to each other about a pivot axis that is oriented differently from that shown.

As mentioned above, the jaw portion **811a** is pivotably coupled to the shaft portion **811b** by the hinge portion **811c**. Specifically, the jaw portion **811a** is pivotable relative to the shaft portion **811b** about a pivot axis B, which may be positioned at any location on or between the jaw portion **811a** and the shaft portion **811b**, and at any circumferential location relative to the jaw portion **811a** and the shaft portion **811b**. In the example embodiment shown, the pivot axis B is oriented vertically, and within the page, in the view shown. In this arrangement, the jaw portion **811a** and the shaft portion **811b** are configured such that, upon articulation of the jaw portion **811a** relative to the shaft portion **811b** and at any point in the movement of the jaw portion **811a** relative to the shaft portion **811b**, the jaw portion **811a** and the shaft portion **811b** remain within a plane that is perpendicular to the pivot axis B. It should be recognized that, in other example embodiments, the pivot axis B may have a different orientation, so as to

54

enable the jaw portion **811a** to pivot within a different plane. The jaw portion **811a** may be pivotable to and between any angles relative to the shaft portion **811b**, such that the jaw portion **811a** can be selectively positioned as desired during use.

Furthermore, the surgical device **800** may provide rotation of various components about a longitudinal axis of the surgical device **800**. For example, in various embodiments, the jaw and/or shaft portions **811a**, **811b** may be rotatable relative to a handle **8103** (described in additional detail below), that is attached to a proximal end of the shaft portion **811b**, about a longitudinal axis D of the handle **8103**, e.g., the longitudinal axis D of the handle **8103** at the point where the handle **8103** meets the shaft portion **811b**. The shaft portion **811b** may include a distal portion **8101a**, to which the jaw portion **811a** is connected, and a proximal portion **8101b**, which may be connected to the handle **8103**.

Generally, the handle **8103** may be grasped by an operator to operate the surgical device **800**. The handle **8103** has a proximal portion **8102**, which in the embodiment shown, forms a base. In addition, the handle **8103** has an intermediate portion **8104**, which includes several finger-actuated control buttons **8107**, **8108** and rocker devices **8117**, **8118**. Still further, the handle **8103** has a distal portion **8105** that is connected to the shaft portion **811b**.

FIG. 17(b) is a partial cutaway view of the surgical device **800**, showing additional details of the components internal to the handle **8103**. As shown, the proximal portion **8102** of the handle **8103** provides a housing in which a power source, e.g., a battery **8106**, may be situated. The battery **8106** may be configured to supply power to any of the components of the surgical device **800**. As set forth above, this arrangement may provide an advantage over other surgical devices in that attachment of the surgical device **800** to a power source of a separate electro-mechanical surgical system may be eliminated.

Likewise, the intermediate portion **8104** of the handle **8103** provides a housing in which a circuit board **8109** may be situated. The circuit board **8109** may be configured to control the various operations of the surgical device **800**, as set forth in additional detail below. As set forth above, this arrangement may provide an advantage over other surgical devices in that attachment of the surgical device **800** to a control system, e.g., software and the like, of a separate electro-mechanical surgical system may be eliminated.

Located on the proximal side of the intermediate portion **8104** of the handle **8103** are control buttons **8107**, **8108** and rocker devices **8117**, **8118**. Each one of the control buttons **8107**, **8108** and rocker devices **8117**, **8118** include a respective magnet that is moved by the actuation of an operator. In addition, the circuit board **8109** includes, for each one of the control buttons **8107**, **8108** and rocker devices **8117**, **8118**, respective Hall-effect switches that are actuated by the movement of the magnets in the control buttons **8107**, **8108** and rocker devices **8117**, **8118**. For example, located immediately proximal to the control button **8107** is a Hall-effect switch that is actuated upon the movement of a magnet within the control button **8107** upon the operator actuating the control button **8107**. The actuation of the Hall-effect switch causes the circuit board **8109** to provide appropriate signals to a function selection module **8210** and an input drive component **8310** (explained further below) to close the first jaw **850** relative to the second jaw **880** and/or to fire a stapling/cutting cartridge within the second jaw **880**.

Also, located immediately proximal to the rocker device **8117** is a Hall-effect switch that is actuated upon the movement of a magnet within the rocker device **8117** upon the

55

operator actuating the rocker device **8117**. The actuation of the Hall-effect switch causes the circuit board **8109** to provide appropriate signals to the function selection module **8210** and the input drive component **8310** to articulate the jaw portion **811a** relative to the shaft portion **811b**. Advantageously, movement of the rocker device **8117** in a first direction may cause the jaw portion **811a** to articulate relative to the shaft portion **811b** in a first direction, while movement of the rocker device **8117** in an opposite, e.g., second, direction may cause the jaw portion **811a** to articulate relative to the shaft portion **811b** in an opposite, e.g., second, direction.

Furthermore, located immediately proximal to the control button **8108** is a Hall-effect switch that is actuated upon the movement of a magnet within the control button **8108** upon the operator actuating the control button **8108**. The actuation of the Hall-effect switch causes the circuit board **8109** to provide appropriate signals to a function selection module **8210** and an input drive component **8310** to open the first jaw **850** relative to the second jaw **880**.

In addition, located immediately proximal to the rocker device **8118** is a Hall-effect switch that is actuated upon the movement of a magnet within the rocker device **8118** upon the operator actuating the rocker device **8118**. The actuation of the Hall-effect switch causes the circuit board **8109** to provide appropriate signals to the function selection module **8210** and the input drive component **8310** to rotate the shaft portion **811b**, or at least a portion thereof, relative to the handle **8103**. Advantageously, movement of the rocker device **8118** in a first direction may cause the shaft portion **811b**, or at least a portion thereof, to rotate relative to the handle **8103** in a first direction, while movement of the rocker device **8118** in an opposite, e.g., second, direction may cause the shaft portion **811b**, or at least a portion thereof, to rotate relative to the handle **8103** in an opposite, e.g., second, direction.

Still further, the distal portion **8105** of the handle **8103** provides a housing in which a drive mechanism **8110** may be situated. The drive mechanism **8110** may be configured to drive shafts and/or gear components in order to perform the various operations of the surgical device **800**, as set forth above. For example, the drive mechanism **8110** may be configured to drive shafts and/or gear components in order to selectively move the jaw portion **811a** relative to the shaft portion **811b**, to rotate the shaft portion **811b** (or portions of the surgical device **800** that are distal thereto) about longitudinal axis D relative to the handle **8103**, to move the first jaw **850** relative to the second jaw **880**, and/or to fire a stapling and cutting cartridge within the second jaw **880**. As set forth above, this arrangement may provide an advantage over other surgical devices in that attachment of the surgical device **800** to a drive system, e.g., motors, etc., of a separate electro-mechanical surgical system may be eliminated.

FIG. 17(c) is a partially cutaway, top perspective view of the surgical device **800**, which illustrates additional details of the drive mechanism **8110**. As shown in FIG. 17(c), the drive mechanism **8110** may include a selector gearbox assembly **850** that is located immediately proximal relative to the shaft portion **811**. Proximal to the selector gearbox assembly **850** is a function selection module **8210** that functions to selectively move gear elements within the selector gearbox assembly **850** into engagement with an input drive component **8310**.

FIGS. 18(a) through 18(d) illustrate various views of the selector gearbox assembly **850**. Specifically, FIG. 18(a) is an exploded perspective view of the selector gearbox assembly **850**. Referring to FIG. 18(a), the sga **850** includes a pair of screws **8101** and **8102**. Each one of the pair of screws **8101** and **8102** are received within respective openings of a proximal housing **826**. In addition, a bearing **801** is seated within a

56

correspondingly shaped recess of the proximal housing **826**. The proximal housing **826** also has a pair of adjacent and overlapping recesses **8261**, **8262** in its distal face. A first recess **8261** is configured to receive a spur gear **839** having gear teeth about its outer circumference. In addition, the spur gear **839** has a centrally-disposed orifice **8391** extending therethrough, the centrally-disposed orifice **8391** defining an opening that has an elongated, slotted shape. A second recess **8262** is configured to receive a spur gear **840** having gear teeth about its outer circumference. In addition, the spur gear **840** has a centrally-disposed orifice **8401** extending therethrough, the centrally-disposed orifice **8401** defining a non-circular opening. The gear teeth of the spur gear **839** are meshingly engaged with the gear teeth of the spur gear **840**. Located distally relative to the spur gears **839**, **840** is a spacer element **883**.

Located distally relative to the spacer element **883** is a spur gear **836** having gear teeth about its outer circumference. In addition, the spur gear **836** has a centrally-disposed orifice **8361** extending therethrough. The centrally-disposed orifice **8361** defines an opening that has longitudinally-extending slots positioned at various intervals along its inner circumferential surface. The selector gearbox assembly **850** also includes a spur gear **838** having gear teeth about its outer circumference. In addition, the spur gear **838** has a centrally-disposed orifice **8381** extending therethrough, the centrally-disposed orifice **8381** defining a non-circular opening. The gear teeth of the spur gear **836** are meshingly engaged with the gear teeth of the spur gear **838**. Located distally relative to the spur gear **838** is a bearing **802**. The bearing **802**, as well as the spur gears **836**, **838** are maintained within respective recesses of a first intermediate housing **825**.

Located distally relative to the first intermediate housing **825** is a spur gear **837** having gear teeth about its outer circumference. In addition, the spur gear **837** has a centrally-disposed orifice **8371** extending therethrough. The centrally-disposed orifice **8371** defines an opening that has longitudinally-extending slots positioned at various intervals along its inner circumferential surface. The selector gearbox assembly **850** also includes a spur gear **834** having gear teeth about its outer circumference. In addition, the spur gear **834** has a centrally-disposed orifice **8341** extending therethrough, the centrally-disposed orifice **8341** defining a non-circular opening. The gear teeth of the spur gear **837** are meshingly engaged with the gear teeth of the spur gear **834**. Located distally relative to the spur gears **834**, **837** is a spacer **882**.

Located distally relative to the spacer element **882** is a spur gear **896** having gear teeth about its outer circumference. In addition, the spur gear **896** has a centrally-disposed orifice **8961** extending therethrough. The centrally-disposed orifice **8961** defines an opening that has longitudinally-extending slots positioned at various intervals along its inner circumferential surface. The selector gearbox assembly **850** also includes a spur gear **895** having gear teeth about its outer circumference. In addition, the spur gear **895** has a centrally-disposed orifice **8951** extending therethrough, the centrally-disposed orifice **8951** defining a non-circular opening. The gear teeth of the spur gear **896** are meshingly engaged with the gear teeth of the spur gear **895**. Located distally relative to the spur gears **895**, **896** are bearings **8031**, **8032**. The bearings **8031**, **8032**, as well as the spur gears **895**, **896** are maintained within respective recesses of a second intermediate housing **824**.

The second intermediate housing **824** also has a pair of adjacent and overlapping recesses **8241**, **8242** in its distal face. A first recess **8241** is configured to receive a spur gear **876** having gear teeth about its outer circumference. In addi-

tion, the spur gear **876** has a centrally-disposed orifice **8761** extending therethrough, the centrally-disposed orifice **8761** defining an opening that has longitudinally-extending slots positioned at various intervals along its inner circumferential surface. A second recess **8242** is configured to receive a spur gear **875** having gear teeth about its outer circumference. In addition, the spur gear **875** has a centrally-disposed orifice **8751** extending therethrough, the centrally-disposed orifice **8751** defining a non-circular opening. The gear teeth of the spur gear **876** are meshingly engaged with the gear teeth of the spur gear **875**.

Located distally relative to the spur gears **875**, **876** are bearings **804**, **8051** and **8052**. The bearings **804**, **8051** and **8052** are maintained within respective recesses of a distal housing **823**. The proximal housing **826**, the first intermediate housing **825**, the second intermediate housing **824** and the distal housing **823** are attached to each other via screws **8101** and **8102** from the proximal end of the selector gearbox assembly **850** and via screws **8111** and **8112** (maintained in sleeves **8321** and **8322**, respectively) from the distal end thereof.

The selector gearbox assembly **850** also includes a selector rod **827**. The selector rod has a head **8271** at its proximal end. The head **8271** is configured to engage the shaft **8211** of the function selection module **8210**. In addition, the selector rod **827** includes a proximal portion **8272**. The proximal portion **8272** has oppositely-disposed flat portions **8273** along its outer circumference. The proximal portion **8272** resides within the opening **8391** of the spur gear **839**, the flat portions **8273** being keyed therewithin such that the selector rod **827** is locked into rotatable engagement with the spur gear **839**. The selector rod **827** also includes oppositely-disposed nubs **828** at about its axial midpoint. The nubs **828** extend radially outwardly from the outer circumference of the selector rod **827**.

In operation, the jaw portion **811a** is maintained in an initial position in which it is axially aligned with the shaft portion **811b**, such as a position similar to the position shown in FIG. 3(b). In this position, the surgical device **800** may be inserted, e.g., through a trocar, into a surgical site. Depending on the position of the incision and the tissue to be clamped, stapled and cut, the user may then operate the surgical device **800**.

Once the surgical device **800** has been inserted within a patient, the shaft portion **811b**, or at least a portion thereof, may be rotated, e.g., the shaft portion **811b** may be rotated relative to and about the longitudinal axis D of the handle **8103**. Of course, it should be recognized that, in the example embodiment described herein, rotation of the shaft portion **811b** relative to the handle **8103** also causes rotation of the jaw portion **811a** disposed distally relative to the shaft portion **811b**. In other embodiments, rotation may be achieved by the jaw portion **811a** rotating relative to and about a longitudinal axis of the shaft portion **811b**, or, in an embodiment in which the jaw portion **811a** is coupled directly to the handle **8103**, by the jaw portion **811a** rotating relative to and about a longitudinal axis of the handle **8103**. For the purposes of this application, the "shaft portion" is intended to refer to any portion of the component of the surgical device that is located distally relative to a handle.

Once the shaft portion **811b** has been rotated relative to the handle **8103**, the surgical device **800** may be employed to move the jaw portion **811a** relative to the shaft portion **811b**, e.g., to pivot the jaw portion **811a** about axis B relative to the shaft portion **811b**. In order to perform this articulation function, the surgical device **800** may be operated such that the function selector module **8210** is moved to an articulation

function position. As set forth above, in this articulation function position, the function selector module **8210** causes engagement of the main drive shaft **8311** of the main motor drive component **8310** with appropriate gears of the selector gearbox assembly **850**, as set forth more fully below.

Generally, the function selector module **8210** is actuated such that the shaft **8211** moves the selector rod **827** to an articulation position. In the embodiment shown, the articulation function position is a position in which the selector rod **827** is moved to its proximal-most position. With the selector rod **827** here, the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8361** of the spur gear **836**.

With the selector rod **827** so positioned, the main motor drive component is then actuated. Specifically, an operator may move the finger-actuated rocker device **8117** in a first direction. The corresponding Hall-effect switch that is located immediately proximal to the rocker device **8117** senses the movement of the magnet in the rocker device **8117** and generates an appropriate signal that is sent to, and received by, the main motor drive component **8310**. The main motor drive component **8310** turns the shafts **8311** in response to the received signals. In an example embodiment, the main motor drive component **8310** may turn the shaft **8311** in a clockwise direction (as previously explained, for the sake of simplicity, all references herein to a rotational direction, e.g., clockwise or counterclockwise, refer to a view from the proximal end of the surgical device towards the distal end of the surgical device **800**, unless otherwise noted; furthermore, it should be recognized that, while the disclosure hereinbelow includes, for each of the components of the surgical device **800**, various references to rotational directions in order to perform a specific function, these directions are merely exemplary because certain components may be differently configured, e.g., threaded portions may have a right-hand thread as opposed to a left-hand thread, etc., such that the rotational directions set forth herein may be reversed in order to perform the same below-described functions).

The distal end of the shaft **8311** is keyed to the non-circular opening **8401** of the spur gear **840**, such that clockwise rotation of the shaft **8311** causes the spur gear **840** to rotate in a clockwise direction. Because the gear teeth on the outer circumference of the spur gear **840** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **839**, clockwise rotation of the spur gear **840** causes the spur gear **839** to rotate in a counter-clockwise direction. As set forth above, the proximal portion **8272** of the selector rod **827** is keyed within the non-circular opening **8391** of the spur gear **839**, such that counter-clockwise rotation of the spur gear **839** causes the selector rod **827** to rotate in a counter-clockwise direction. Also, because the selector rod **827** is in an axial position in which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8361** of the spur gear **836**, counter-clockwise rotation of the selector rod **827** causes the spur gear **836** to rotate in a counter-clockwise direction.

Because the gear teeth on the outer circumference of the spur gear **836** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **838**, counter-clockwise rotation of the spur gear **836** causes the spur gear **838** to rotate in a clockwise direction. The non-circular opening **8381** of the spur gear **838** is keyed to a shaft, such as the shaft **525** illustrated in, e.g., FIG. 4(d), such that clockwise rotation of the spur gear **838** causes articulation of the jaw portion **811a** relative to the shaft portion **811b** about axis B in a first, e.g., counter-clockwise direction (when viewed from above) in the manner described hereinabove or in any other manner.

Of course, the movement, e.g., articulation, in the opposite direction may also be accomplished by reversing the direction in which the above-described gears are caused to rotate.

Once the jaw portion **811a** has been articulated about axis B relative to the shaft portion **811b**, the jaws **850**, **880** may be moved, e.g., opened, so as to enable a section of tissue to be disposed therebetween. In order to perform this opening function, the surgical device **800** may be operated such that the function selector module **8210** is moved to an opening function position. As set forth above, in this opening function position, the function selector module **8210** causes engagement of the main drive shaft **8311** of the main motor drive component **8310** with appropriate gears of the selector gear-box assembly **850**, as set forth more fully below.

Generally, the function selector module **8210** is actuated such that the shaft **8211** moves the selector rod **827** to a clamping position. In the embodiment shown, the clamping function position is a position in which the selector rod **827** is moved to an axial position at which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8961** of the spur gear **896**.

With the selector rod **827** so positioned, the main motor drive component **8310** is then actuated. Specifically, an operator may move the finger-actuated control button **8108**. The corresponding Hall-effect switch that is located immediately proximal to the control button **8108** senses the movement of the magnet in the control button **8108** and generates an appropriate signal that is sent to, and received by, the main motor drive component **8310**. The main motor drive component **8310** turns the shaft **8311** in response to the received signals. In an example embodiment, the main motor drive component **8310** may turn the shaft **8311** in a clockwise direction.

Since the distal end of the shaft **8311** is keyed to the non-circular opening **8401** of the spur gear **840**, clockwise rotation of the shaft **8311** causes the spur gear **840** to rotate in a clockwise direction. Also, because the gear teeth on the outer circumference of the spur gear **840** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **839**, clockwise rotation of the spur gear **840** causes the spur gear **839** to rotate in a counter-clockwise direction. As set forth above, the proximal portion **8272** of the selector rod **827** is keyed within the non-circular opening **8961** of the spur gear **896**, such that counter-clockwise rotation of the spur gear **839** causes the selector rod **827** to rotate in a counter-clockwise direction. Also, because the selector rod **827** is in an axial position in which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8961** of the spur gear **896**, counter-clockwise rotation of the selector rod **827** causes the spur gear **896** to rotate in a counter-clockwise direction.

Because the gear teeth on the outer circumference of the spur gear **896** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **895**, counter-clockwise rotation of the spur gear **896** causes the spur gear **895** to rotate in a clockwise direction. The non-circular opening **8951** of the spur gear **895** is keyed to a shaft, such as the shaft **527** illustrated in, e.g., FIG. 4(d), such that clockwise rotation of the spur gear **895** causes the first jaw **850** to move, e.g., be opened, relative to the second jaw **880** in the manner described hereinabove or in any other manner.

Once the first and second jaws **850**, **880** have been opened to a desired position relative to each other, and once a section of tissue desired to be operated on is satisfactorily positioned between the first and second jaws **850**, **880** of the surgical

device **800**, the first and second jaws **850**, **880** are closed so as to clamp the section of tissue therebetween.

In order to close the first and second jaws **50**, **80** relative to each other, the function selector module **8210** may remain in the clamping function position. As set forth above, in this clamping function position, the selector rod **827** is positioned such that the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8961** of the spur gear **896**.

With the selector rod **827** so positioned, the main motor drive component **8310** is then actuated in a reverse direction from that described above. Specifically, an operator may move the finger-actuated control button **8107**. The corresponding Hall-effect switch that is located immediately proximal to the control button **8107** senses the movement of the magnet in the control button **8107** and generates an appropriate signal that is sent to, and received by, the main motor drive component **8310**. The main motor drive component **8310** turns the shaft **8311** in response to the received signals. In this example embodiment, the main motor drive component **8310** may turn the shaft **8311** in a counter-clockwise direction.

Since the distal end of the shaft **8311** is keyed to the non-circular opening **8401** of the spur gear **840**, counter-clockwise rotation of the shaft **8311** causes the spur gear **840** to rotate in a counter-clockwise direction. Also, because the gear teeth on the outer circumference of the spur gear **840** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **839**, counter-clockwise rotation of the spur gear **840** causes the spur gear **839** to rotate in a clockwise direction. As set forth above, the proximal portion **8272** of the selector rod **827** is keyed within the non-circular opening **8391** of the spur gear **839**, such that clockwise rotation of the spur gear **839** causes the selector rod **827** to rotate in a clockwise direction. Also, because the selector rod **827** is in an axial position in which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8961** of the spur gear **896**, clockwise rotation of the selector rod **827** causes the spur gear **896** to rotate in a clockwise direction.

Because the gear teeth on the outer circumference of the spur gear **896** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **895**, clockwise rotation of the spur gear **896** causes the spur gear **895** to rotate in a counter-clockwise direction. The non-circular opening **8951** of the spur gear **895** is keyed to a shaft, such as the shaft **527** illustrated in, e.g., FIG. 4(d), such that counter-clockwise rotation of the spur gear **895** causes the first jaw **850** to move, e.g., be closed, relative to the second jaw **880** in the manner described hereinabove or in any other manner, thereby clamping the section of tissue between the first and second jaws **850**, **880**.

Once a section of tissue has been clamped between the first and second jaws **850**, **880**, the section of tissue may be cut and/or stapled. It should be recognized that, while the present invention is illustrated as using both cutting and stapling elements, the surgical device **800** may employ only one such element, or else may employ a different type of surgical instrument.

Before the surgical device **800** is inserted into a patient's body, a staple cartridge **578** is provided within the second jaw **880**. In an embodiment, the surgical device **800** is a single-use device, in which the staple cartridge is integral to the second jaw **880**. Alternatively, the surgical device **800** may have a replaceable staple cartridge, e.g., replaceable staple cartridge **600** as illustrated in FIG. 4(e), thereby permitting the surgical device **800** to be used numerous times with different staple

61

cartridges. In this embodiment, if the surgical device **800** is being used for the first time, the staple cartridge **600** may be pre-installed during manufacture and assembly of the surgical device **800**, or else may be installed by the user just prior to using the surgical device **800**. If the surgical device **800** is being used for the second or more time, the staple cartridge **600** may be installed by the user just prior to using the surgical device **800**. When the staple cartridge **600** is inserted into the second jaw **880**, the distal end of the firing shaft **557** is received within the proximally-facing opening **605d** of the wedge driver **605**.

With the staple cartridge **600** installed within the second jaw **80** of the surgical device **800**, the surgical device **800** may be operated such that the function selector module **8210** is moved to a firing function position. As set forth above, in this firing function position, the selector rod **827** is positioned such that the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8371** of the spur gear **837**.

With the selector rod **827** so positioned, the main motor drive component **8310** is then actuated. Specifically, an operator may again move the finger-actuated control button **8107**. The corresponding Hall-effect switch that is located immediately proximal to the control button **8107** senses the movement of the magnet in the control button **8107** and generates an appropriate signal that is sent to, and received by, the main motor drive component **8310**. The main motor drive component **8310** turns the shaft **8311** in response to the received signals. In this example embodiment, the main motor drive component **8310** may turn the shaft **8311** in a counter-clockwise direction.

Since the distal end of the shaft **8311** is keyed to the non-circular opening **8401** of the spur gear **840**, counter-clockwise rotation of the shaft **8311** causes the spur gear **840** to rotate in a counter-clockwise direction. Also, because the gear teeth on the outer circumference of the spur gear **840** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **839**, counter-clockwise rotation of the spur gear **840** causes the spur gear **839** to rotate in a clockwise direction. As set forth above, the proximal portion **8272** of the selector rod **827** is keyed within the non-circular opening **8391** of the spur gear **839**, such that clockwise rotation of the spur gear **839** causes the selector rod **827** to rotate in a clockwise direction. Also, because the selector rod **827** is in an axial position in which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8371** of the spur gear **837**, clockwise rotation of the selector rod **827** causes the spur gear **837** to rotate in a clockwise direction.

Because the gear teeth on the outer circumference of the spur gear **837** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **834**, clockwise rotation of the spur gear **837** causes the spur gear **834** to rotate in a counter-clockwise direction. The non-circular opening **8341** of the spur gear **834** is keyed to a shaft, such as the shaft **529** illustrated in, e.g., FIG. 4(d), such that counter-clockwise rotation of the spur gear **834** causes the cutting and/or stapling of the tissue in the manner described hereinabove or in any other manner, e.g., by driving a staple pushing element and/or cutting blade through the section of tissue.

Once the section of tissue is cut and/or stapled, the surgical device **800** may be employed to return the wedge **2603** and the blade **51** to their initial positions. This may be particularly desirable when the surgical device **800** employs replaceable staple cartridges, e.g., replaceable staple cartridge **600** as illustrated in FIG. 4(e), thereby permitting the surgical device **800** to be used numerous times with different staple car-

62

tridges. Once the wedge **2603** and the blade **51** have been moved to their initial positions, the surgical device **800** may be used for a second or more time. To do so, the user may remove the spent staple cartridge **600** and insert in the surgical device **800** a new staple cartridge **600**, the distal end of the firing shaft **557** being received within the proximally-facing opening **2605d** of the wedge driver **2605** of the new staple cartridge **2600**. Of course, it should be recognized that this step of returning the wedge **2603** and the blade **51** to their initial positions may be performed either prior to, or subsequent to, removal of the surgical device **800** from the patient's body.

In order to return the wedge **2603** and the blade **51** to their initial positions, the function selector module **8210** may remain in the firing function position. As set forth above, in this firing function position, the selector rod **827** is positioned such that the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8371** of the spur gear **837**.

With the selector rod **827** so positioned, the main motor drive component **8310** is then actuated in a reverse direction as described above. Specifically, an operator may again move the finger-actuated control button **8107**. The corresponding Hall-effect switch that is located immediately proximal to the control button **8107** senses the movement of the magnet in the control button **8107** and generates an appropriate signal that is sent to, and received by, the main motor drive component **8310**. The main motor drive component **8310** turns the shaft **8311** in response to the received signals. In this example embodiment, the main motor drive component **8310** may turn the shaft **8311** in a clockwise direction.

Since the distal end of the shaft **8311** is keyed to the non-circular opening **8401** of the spur gear **840**, clockwise rotation of the shaft **8311** causes the spur gear **840** to rotate in a clockwise direction. Also, because the gear teeth on the outer circumference of the spur gear **840** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **839**, clockwise rotation of the spur gear **840** causes the spur gear **839** to rotate in a counter-clockwise direction. As set forth above, the proximal portion **8272** of the selector rod **827** is keyed within the non-circular opening **8391** of the spur gear **839**, such that counter-clockwise rotation of the spur gear **839** causes the selector rod **827** to rotate in a counter-clockwise direction. Also, because the selector rod **827** is in an axial position in which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8371** of the spur gear **837**, counter-clockwise rotation of the selector rod **827** causes the spur gear **837** to rotate in a counter-clockwise direction.

Because the gear teeth on the outer circumference of the spur gear **837** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **834**, counter-clockwise rotation of the spur gear **837** causes the spur gear **834** to rotate in a clockwise direction. The non-circular opening **8341** of the spur gear **834** is keyed to a shaft, such as the shaft **529** illustrated in, e.g., FIG. 4(d), such that clockwise rotation of the spur gear **834** causes the cutting and/or stapling elements, e.g., the wedge **2603** and the blade **51**, to be returned to their initial positions in the manner described hereinabove or in any other manner.

Once the wedge **2603** and the blade **51** to their initial positions, the surgical device **800** may be employed to move the jaw portion **811a** relative to the shaft portion **811b**, e.g., to pivot the jaw portion **811a** about axis B relative to the shaft portion **811b**, back to its initial aligned position for the purposes of easing the removal of the surgical device from the

63

incision of the patient. In order to perform this function, the surgical device **800** may be operated such that the function selector module **8210** is moved back to the articulation function position. As set forth above, in this articulation function position, the function selector module **8210** causes engagement of the main drive shaft **8311** of the main motor drive component **8310** with appropriate gears of the selector gear-box assembly **850**, as set forth more fully below.

Generally, the function selector module **8210** is actuated such that the shaft **8211** moves the selector rod **827** back to the articulation function position in which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8361** of the spur gear **836**.

With the selector rod **827** so positioned, the main motor drive component is then actuated in the reverse direction from that described above. Specifically, an operator may move the finger-actuated rocker device **8117** in a second direction. The corresponding Hall-effect switch that is located immediately proximal to the rocker device **8117** senses the movement of the magnet in the rocker device **3117** and generates an appropriate signal that is sent to, and received by, the main motor drive component **8310**. The main motor drive component **8310** turns the shafts **8311** in response to the received signals. In an example embodiment, the main motor drive component **8310** may turn the shaft **8311** in a counter-clockwise direction. The distal end of the shaft **8311** is keyed to the non-circular opening **8401** of the spur gear **840**, such that counter-clockwise rotation of the shaft **8311** causes the spur gear **840** to rotate in a counter-clockwise direction. Because the gear teeth on the outer circumference of the spur gear **840** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **839**, counter-clockwise rotation of the spur gear **840** causes the spur gear **839** to rotate in a clockwise direction. As set forth above, the proximal portion **8272** of the selector rod **827** is keyed within the non-circular opening **8391** of the spur gear **839**, such that clockwise rotation of the spur gear **839** causes the selector rod **827** to rotate in a clockwise direction. Also, because the selector rod **827** is in an axial position in which the nubs **828** of the selector rod **827** are positioned within the longitudinal slots located on the inner circumferential surface of the opening **8361** of the spur gear **836**, clockwise rotation of the selector rod **827** causes the spur gear **836** to rotate in a clockwise direction.

Because the gear teeth on the outer circumference of the spur gear **836** are meshingly engaged with the gear teeth on the outer circumference of the spur gear **838**, clockwise rotation of the spur gear **836** causes the spur gear **838** to rotate in a counter-clockwise direction. The non-circular opening **8381** of the spur gear **838** is keyed to a shaft, such as the shaft **525** illustrated in, e.g., FIG. 4(d), such that counter-clockwise rotation of the spur gear **838** causes articulation of the jaw portion **811a** relative to the shaft portion **811b** about axis B in the second, e.g., clockwise direction (when viewed from above) in the manner described hereinabove or in any other manner. Of course, the movement, e.g., articulation, in the opposite direction may also be accomplished by reversing the direction in which the above-described gears are caused to rotate.

Once the longitudinal axes of the jaw portion **811a** and the shaft portion **811b** have been aligned, the surgical device **800** may be employed to return the shaft portion **811b** to its initial position relative to the handle **8103**, e.g., by rotating the shaft portion **811b** relative to the handle **8103** about the longitudinal axis D of the handle **8103** until the shaft portion **811b** and the handle **8103** are in their initial, e.g., aligned, positions relative to each other. Again, this may be particularly desir-

64

able when the surgical device **800** employs replaceable staple cartridges, e.g., replaceable staple cartridge **600** as illustrated in FIG. 4(e), so as to return the surgical device **800** into a condition which permits it to be used numerous times with different staple cartridges. Once the shaft portion **811b** has been rotated back to its initial position relative to the handle **8103**, the surgical device **800** may be used for a second or more time. Of course, it should be recognized that this particular step may be performed either prior to, or subsequent to, removal of the surgical device **800** from the patient's body.

Those skilled in the art will appreciate that numerous modifications of the exemplary embodiment described hereinabove may be made without departing from the spirit and scope of the present invention. Although exemplary embodiments of the present invention have been described and disclosed in detail herein, it should be understood that this invention is in no sense limited thereby.

What is claimed is:

1. A surgical device comprising:

a jaw portion having a first jaw and a second jaw;
a shaft assembly coupled to a proximal end of the jaw portion, the shaft assembly defining a longitudinal axis;
a handle assembly supporting the jaw assembly; and
a drive assembly supported in the handle assembly, the drive assembly being configured to apply a plurality of control motions to the shaft assembly;

wherein the drive assembly includes a gear train operably communicating with a firing input bevel gear for actuating at least one gear of the gear train to transversely communicate with at least one other gear of the gear train; and

wherein the gear train includes a first bevel gear and a second bevel gear, the first and second bevel gears being coaxial with the longitudinal axis defined by the shaft assembly.

2. The surgical device according to claim 1, wherein the gear train further includes a first articulation gear, a portion of the first articulation gear being disposed between the first and second bevel gears.

3. The surgical device according to claim 2, wherein the first articulation gear is transverse to the first and second bevel gears.

4. The surgical device according to claim 3, wherein the first articulation gear operably communicates with a second articulation gear, the first and second articulation gears disposed in a coaxial relationship.

5. The surgical device according to claim 1, wherein the first and second bevel gears are idler gears.

6. The surgical device according to claim 1, wherein the first and second bevel gears are transverse to the firing input bevel gear.

7. The surgical device according to claim 1, wherein the first and second bevel gears are transverse to an articulation shaft disposed through the shaft assembly.

8. The surgical device according to claim 1, wherein the gear train includes a bevel/spur gear component.

9. The surgical device according to claim 8, wherein the bevel/spur gear component is transverse with at least one of the first or second bevel gears.

10. The surgical device according to claim 1, wherein the first and second bevel gears define a pivot axis therethrough.

11. The surgical device according to claim 10, wherein the pivot axis is perpendicular to the longitudinal axis defined by the shaft assembly.

65

12. A surgical device comprising:
 a jaw portion;
 a shaft assembly coupled to the jaw portion, the shaft
 assembly defining a longitudinal axis therethrough;
 a handle assembly supporting the shaft assembly; and
 a drive assembly supported in the handle assembly, the
 drive assembly mechanically cooperating with the shaft
 assembly, the drive assembly including a first gear
 arrangement transversely engaging a second gear
 arrangement;
 wherein the first gear arrangement includes a first bevel
 gear and the second gear arrangement includes a second
 bevel gear, the first and second bevel gears being coaxial
 with the longitudinal axis defined by the shaft assembly.
13. The surgical device according to claim 12, wherein the
 second gear arrangement operably communicates with a first
 articulation gear, a portion of the first articulation gear dis-
 posed between the first and second bevel gears.
14. The surgical device according to claim 13, wherein the
 second gear arrangement operably communicates with a sec-

66

ond articulation gear meshingly engaged with the first articu-
 lation gear, the first and second articulation gears disposed in
 a coaxial relationship.

15. The surgical device according to claim 12, wherein the
 first and second bevel gears are idler gears.

16. The surgical device according to claim 12, wherein the
 first and second bevel gears are transverse to a firing input
 bevel gear operably communicating with the drive assembly.

17. The surgical device according to claim 12, wherein the
 first and second bevel gears are transverse to an articulation
 shaft disposed through the shaft assembly.

18. The surgical device according to claim 12, further
 comprising a third gear arrangement, the third gear arrange-
 ment including at least a bevel/spur gear component.

19. The surgical device according to claim 18, wherein the
 bevel/spur gear component is transverse with at least one of
 the first or second bevel gears of the first gear arrangement.
